# Native Spaces

See e.g [Buhmann 2003], [Fasshauer 2007], [Wendland 2005]

Let  $H$  be an Hilbert space and  $\Omega \subset \mathbf{R}^d$ .

- ▶ The function

$$K : \Omega \times \Omega \rightarrow \mathbf{R}$$

is called reproducing kernel for  $H$  if

$$K(x, \cdot) \in H \quad \forall x \in \Omega,$$

and

$$f(x) = (f, K(x, \cdot))_H \text{ for all } x \in \Omega, f \in H.$$

- ▶ The kernel is positive definite, if for all choices of sets of knots

$$\{x_1, \dots, x_N \in \Omega\},$$

the *kernel matrices* with elements  $K(x_i, x_j)$ ,  $1 \leq i, j \leq N$  are positive definite.

- ▶ For  $K$  positive definite, we define the *native space*

$$\mathcal{H}(K, \Omega) = \text{span}\{K(x, \cdot), x \in \Omega\}.$$

- ▶ If the kernel is *radial*, i.e. of the form

$$K(x, y) = \phi(\|x - y\|_2)$$

for a scalar function

$$\phi : [0, \infty) \rightarrow \mathbf{R},$$

the function  $\phi$  is called a *radial basis function*.

# Interpolation

Given a set

$$X = \{x_1, \dots, x_N\} \subset \Omega,$$

and the associated values

$$f = [f(x_1), \dots, f(x_n)]^T,$$

the goal is to find a continuous function

$$P_f : \mathbf{R}^d \rightarrow \mathbf{R}$$

such that

$$P_f(x_i) = f(x_i), \quad i = 1, \dots, N.$$

In the RBF literature

$$P_f(x) = \sum_{i=1}^N a_i \phi(\|x - x_i\|),$$

where the coefficients are the solution of the linear system

$$a = A^{-1}f,$$

and

$$A_{ij} = \phi(\|x_i - x_j\|).$$

Variably scaled kernels

Introduction

Definition

Numerical Examples

Improving the stability

Reproduction quality

Given a domain  $\Omega \subset \mathbf{R}^d$ , we consider a bijective map

$$C : \Omega \mapsto C(\Omega).$$

Given a kernel

$$K : \Omega \times \Omega \rightarrow \mathbf{R}$$

and the map  $C$ , the kernel

$$K_C(C(x), C(y)) := K(x, y) \text{ for all } x, y \in \Omega$$

acts on  $C(\Omega)$  and inherits the definiteness properties of  $K$ .

This gives rise to two native spaces and their properties, i.e.

- ▶ the space  $\mathcal{H}(K, \Omega)$

$$\begin{aligned} f(x) &= (f, K(x, \cdot)) \\ K(x, y) &= (K(x, \cdot), K(y, \cdot)) \end{aligned}$$

for all  $x, y \in \Omega$ .

- ▶ The space  $\mathcal{H}_C(K_C, C(\Omega))$

$$\begin{aligned} g(u) &= (g, K_C(u, \cdot))_{\mathcal{H}_C} \\ K_C(u, v) &= (K_C(u, \cdot), K_C(v, \cdot))_{\mathcal{H}_C} \end{aligned}$$

for all  $u, v \in C(\Omega)$ .

We indicate by  $\mathcal{C}$  the map

$$\mathcal{C} : f \text{ on } \Omega \rightarrow g \text{ on } C(\Omega)$$

such that

$$g(C(x)) = (\mathcal{C}f)(C(x)) := f(x).$$

Furthermore,

$$\begin{aligned} \mathcal{C}(K(\cdot, y))(C(x)) &:= K(x, y) \\ &= K_C(C(x), C(y)). \end{aligned}$$

The map  $\mathcal{C}$  is linear.

- ▶ The two native spaces  $\mathcal{H}$  and  $\mathcal{H}_C$  are isometric:

$$\begin{aligned} (K(x, \cdot), K(y, \cdot))_{\mathcal{H}} &= K(x, y) \\ &= K_C(C(x), C(y)) \\ &= (K_C(C(x), \cdot), K_C(C(y), \cdot))_{\mathcal{H}_C} \end{aligned}$$

It follows that

$$(f, g)_{\mathcal{H}} = (\mathcal{C}f, \mathcal{C}g)_{\mathcal{H}_C}.$$

# Summarizing

Let

$$C : \Omega \mapsto C(\Omega).$$

be a bijective map and

$$K : \Omega \times \Omega \rightarrow \mathbf{R}$$

a positive definite kernel.

- ▶ We introduce the transformed kernel  $K_C(C(x), C(y))$  which inherits the definiteness property of  $K$ .
- ▶ The native spaces  $\mathcal{H}(K, \Omega)$ ,  $\mathcal{H}_C(K_C, C(\Omega))$  are isometric.

# Definition and Properties

Let

$$C : x \in \Omega \subset \mathbf{R}^d \mapsto (x, c(x)) \in C(\Omega) \subset \mathbf{R}^{d+1}$$

where

$$c : \mathbf{R}^d \mapsto (0, \infty).$$

- ▶ Let  $K$  a positive definite kernel on  $\mathbf{R}^{d+1}$

$$K_c(x, y) := K((x, c(x)), (y, c(y))) \quad x, y \in \mathbf{R}^d.$$

$K_c$  is the *Variably scaled kernel*

- ▶ Since  $K$  is positive definite on the submanifold, so is  $K_c$ .
- ▶ If  $K$  and  $c$  are continuous, so is  $K_c$ .

Therefore, given the set  $X := \{x_1, \dots, x_N\}$  on  $\mathbf{R}^d$ , the matrix

$$A_{c,X} := (K_c(x_i, x_j))_{1 \leq i, j \leq N}$$

is non singular and the interpolant is

$$P_f(x) := \sum_{j=1}^N a_j K_c(x, x_j) = \sum_{j=1}^N a_j K((x, c(x)), (x_j, c(x_j))).$$

If the kernel is radial, i.e.  $K(x, y) = \phi(\|x - y\|_2^2)$ , the interpolant is

$$P_f := \sum_{j=1}^N a_j \phi(\|x - x_j\|_2^2 + (c(x) - c(x_j))^2).$$

# Examples

If  $K$  is a power kernel  $\phi(r) = r^\beta$ , the interpolants take the form

$$P_f(x) := \sum_{j=1}^N a_j (\|x_j - x\|_2^2 + (c(x_j) - c(x))^2)^{\beta/2}$$

and are identical to power interpolants if the scale function  $c(x)$  is constant, otherwise similar to scaled multiquadrics.

If  $K$  is the Gaussian.

$$\begin{aligned} P_f(x) &= \sum_{j=1}^N a_j \exp(-\|x_j - x\|_2^2 - (c(x_j) - c(x))^2) \\ &= \sum_{j=1}^N a_j \exp(-\|x_j - x\|_2^2) \exp(-(c(x_j) - c(x))^2) \end{aligned}$$

which can be seen as a superposition of Gaussians of the same scale but with varying amplitudes for evaluation.

We observe that

- ▶ the analysis of error and stability of the varying-scale problem in  $\mathbf{R}^d$  coincides with the analysis of a fixed-scale problem on a submanifold in  $\mathbf{R}^{d+1}$ .
- ▶ In particular, let  $\Omega$  be a compact set and  $C$  be a diffeomorphism between  $\Omega$  and  $C(\Omega)$ , then  $C(\Omega)$  is compact.

As usual, we consider the *fill distance*

$$h(X, \Omega) := \sup_{y \in \Omega} \min_{x \in X} \|x - y\|_2$$

and the *separation distance*

$$q(X) := \min_{X \ni x \neq y \in X} \|x - y\|_2$$

Then

$$q(C(\Omega)) = \min \|C(x) - C(y)\|_2$$

and

$$\begin{aligned}\|C(x) - C(y)\|_2^2 &= \|x - y\|_2^2 + (c(x) - c(y))^2 \\ &\leq \|x - y\|_2^2 (1 + L)^2 \\ \|C(x) - C(y)\|_2^2 &\geq \|x - y\|_2^2\end{aligned}$$

$L$  is a constant related to the norm of the gradient of  $c$ .

It follows that *the separation distance never decreases*.

# Numerical examples

We now provide some examples that show the different roles of the variable scale parameter: it may affect both the stability and the accuracy.

- ▶ Its appropriate choice enhances stability,
- ▶ one can significantly improve the recovery quality, in particular by preserving shape properties in a much better way than for interpolation with constant scale.

# Chebyshev Points

We chose the Gaussian kernel at fixed scale  $0.1/\sqrt{2}$  and took  $N=55$  Chebyshev points  $\Omega = [-1, +1]$  from Runge function

$$f(x) = 1/(1 + 25x^2).$$

We map the interval  $\Omega = [-1, +1] \subset \mathbf{R}$  to the semi-circle  $C(\Omega) \subset \mathbf{R}^2$  via

$$C(x) = (x, \sqrt{1 - x^2}).$$

The  $L_\infty$  errors and condition numbers are

Points and scaling	Condition	no noise	0.001 noise
Chebyshev, single scale	$1 \cdot 10^{16}$	$1.1 \cdot 10^{-5}$	1.4294
Chebyshev, variable scale	$8 \cdot 10^5$	$1.3 \cdot 10^{-4}$	0.0012

Table: Interpolation of Runge function by Gaussians

# Cluster of data

We take  $N = 47$  points  $x_i \in [-1, 1]$  so that 41 nodes are equispaced in the interval and 6 close to 0.4, with mutual distance  $q = 10^{-4}$ .

As  $c(x)$ , we consider the *skew-Gaussian*

Figure:  $C(x) = (x, c(x))$  with some  $c(x_i)$  values

In this table, we show the condition numbers and the  $L_\infty$  errors obtained interpolating the Runge function by the Gaussian kernel at fixed scale  $0.1/\sqrt{2}$  and by the proposed technique (VSK).

Points and scaling	Condition	error	0.001 noise
cluster, single scale	$3.5 \cdot 10^{16}$	$6.02 \cdot 10^{-5}$	$5.4 \cdot 10^{-1}$
cluster, variable scale	$6.9 \cdot 10^{10}$	$9.4 \cdot 10^{-6}$	$3.0 \cdot 10^{-3}$

**Table:** Interpolation of Runge function by Gaussians, cluster nodes

## Plots of the absolute error for the two interpolants

**Figure:** No noise case; absolute error for the classic case in red; absolute error for the VSK-interpolant in blue

Now, we deal with the problem of obtaining interpolants which reproduce faithfully the underlying functions.

(see e.g. [B., Lenarduzzi 2003], [Casciola et al. 2006]).

In the following examples, we compare

- ▶ the classical interpolant provided by the  $C^2$  Wendland kernel with support radius 1
- ▶ the VSK interpolation provided by the  $d$ -variate  $C^2$  Wendland kernel with support radius  $\mu(C(\Omega))^{1/d}$ , where  $\mu$  is the length or area of  $C(\Omega)$ .

# The logistic function

We consider the logistic function

$$f(x) = (1 + 2 \cdot \exp(p(x)))^{-0.5}$$

where  $p(x) = -3 \cdot (10\sqrt{2x^2} - 6.7)$ . We take  $N = 11$  nodes in the interval  $\Omega = [0, 1]$ .

$$c(x) = 2 \cdot s_{MQ}(x).$$

Figure:  $C(x) = (x, c(x))$

Figure: Classical Wendland interpolant: black line; logistic function: blue line

Figure: VSK-interpolant: black line; logistic function: blue line

The  $L_\infty$  errors are  $2.5 \cdot 10^{-2}$  for the fixed-scale case and  $6.4 \cdot 10^{-3}$  for the variable-scale case.

**Figure:** Absolute error for the classic interpolant: red; absolute error for the VSK interpolant: blue
