

# CS640: Introduction to Computer Networks

Aditya Akella

Lecture 20 - QoS

---

---

---

---

---

---

---

---

## Why a New Service Model?

- Best effort clearly insufficient
  - Some applications need more assurances from the network
- What is the **basic objective** of network design?
  - Maximize total bandwidth? Minimize latency?
  - **Maximize user satisfaction** - the total **utility** given to users
- What does utility vs. bandwidth look like?
  - Must be non-decreasing function
  - Shape depends on application

2

---

---

---

---

---

---

---

---

## Utility curve - Elastic traffic

Does equal allocation of bandwidth maximize total utility?

3

---

---

---

---

---

---

---

---

## Admission Control

- If  $U(\text{bandwidth})$  is concave  
→ elastic applications

- Incremental utility is decreasing with increasing bandwidth
- Is always advantageous to have more flows with lower bandwidth
  - No need of admission control and explicit QoS mechanisms

4

---

---

---

---

---

---

---

---

## Utility Curves - Inelastic traffic

Does equal allocation of bandwidth maximize total utility?

5

---

---

---

---

---

---

---

---

## QoS and Admission Control

- If  $U$  is convex → inelastic applications

- $U(\text{number of flows})$  is no longer monotonically increasing

- Need admission control and special QoS mechanisms

- Admission control → deciding when the addition of new people would result in reduction of utility

6

---

---

---

---

---

---

---

---

## QoS Instantiation #1: Integrated Services

Key components:

1. Type of commitment  
What does the network promise?
2. Packet scheduling  
How does the network meet promises?
3. Service interface  
How does the application describe what it wants?

7

---

---

---

---

---

---

---

---

## Type of Commitments

- **Guaranteed service**
  - For **hard real-time** applications
  - Fixed guarantee, network meets commitment as long as rates clients send at match traffic agreement
- **Predicted service**
  - For tolerant (e.g. delay-adaptive) applications
  - Two components
    - If conditions do not change, commit to current service
    - If conditions change, take steps to deliver consistent performance (help apps minimize playback delay). Ensure that such apps continue to see a lightly loaded network.
- **Datagram/best effort service**

8

---

---

---

---

---

---

---

---

## Scheduling for Guaranteed Traffic

- Use **token bucket filter** to characterize traffic
  - Described by rate  $r$  and bucket depth  $b$
  - FlowSpec or flow specification
- Use **Weighted Fair-Queueing** at the routers
- Parekh's bound for worst case queuing delay =  $b/r$

9

---

---

---

---

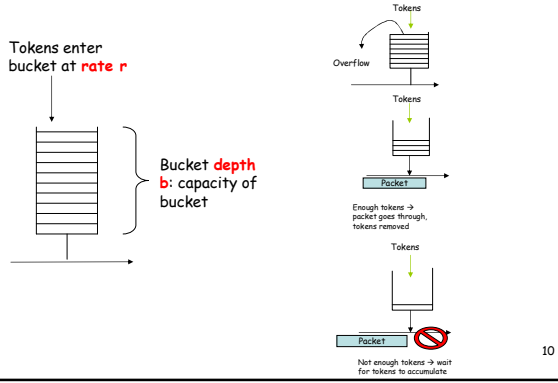

---

---

---

---

## Token Bucket Filter

---

---

---

---

---

---

---

---

## Token Bucket Characteristics

- On the long run, rate is limited to  $r$
- On the short run, a burst of size  $b$  can be sent
- Amount of traffic entering at interval  $T$  is bounded by:
  - Traffic =  $b + r \cdot T$

11

---

---

---

---

---

---

---

---

## Token Bucket Specs

12

---

---

---

---

---

---

---

---

## Guarantee Proven by Parekh

- Given:
  - Flow  $i$  shaped with token bucket and leaky bucket rate control (depth  $b$  and rate  $r$ )
  - Network nodes do WFQ
- Cumulative queuing delay  $D_i$  suffered by flow  $i$  has upper bound
  - $D_i < b/r$

13

---

---

---

---

---

---

---

---

## Putting It All Together

- Assume 3 types of traffic: guaranteed, predictive, best-effort
- Scheduling: use WFQ in routers
- Each guaranteed flow gets its own queue
- All predicted service flows and best effort aggregates in single separate priority queue
  - Predictive traffic classes
    - Worst case delay for classes separated by order of magnitude
    - Strict priority queuing - coupled with admission control into each priority level
    - Higher priority steals scheduling cycles from lower priority - One way isolation
  - Best effort traffic acts as lowest priority class

14

---

---

---

---

---

---

---

---

## Resource Reservation Protocol (RSVP)

- Carries resource requests all the way through the network
- Main goal: establish "state" in each of the routers so they "know" how they should treat flows.
  - State = packet classifier parameters, bandwidth reservation, ..
- At each hop consults admission control and sets up reservation. Informs requester if failure
- Key properties
  - Receiver driven
  - Soft state
    - Periodically refresh reservations

15

---

---

---

---

---

---

---

---

## PATH Messages

- PATH messages carry sender's flow properties
- Routers note the direction PATH messages arrived and set up *reverse path* to sender
- Receivers send RESV messages that follow reverse path and setup reservations
- If reservation cannot be made, user gets an error

16

---

---

---

---

---

---

---

---

## RESV Messages

- Forwarded via reverse path of PATH
- Queuing delay and bandwidth requirements
- Source traffic characteristics (from PATH)
- Filter specification
  - Which transmissions can use the reserved resources
- Router performs admission control and reserves resources
  - If request rejected, send error message

17

---

---

---

---

---

---

---

---

## Differentiated Services: Motivation and Design

- Edge routers do coarse grain enforcement
  - Label packets with a type field
    - Uses IP TOS bits
    - E.g. a priority stamp
- Core routers process packets based on packet marking
- More scalable than IntServ
  - No signaling
  - No per-flow state in the core
  - More useful between a pair of neighboring networks, while IntServ was end-to-end
  - Typically used by multi-campus enterprises with all campuses connected to the same ISP

18

---

---

---

---

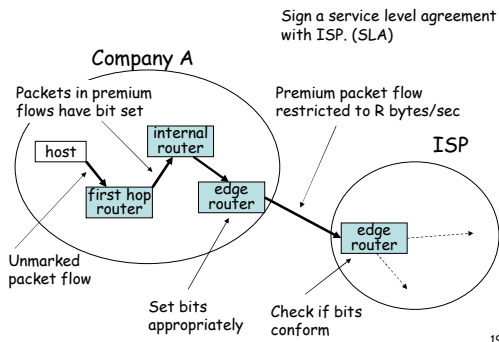

---

---

---

---

## DiffServ Example

---

---

---

---

---

---

---

---

## Expedited Forwarding

User sends within agreed profile & network commits to delivery with requested profile

- Strong guarantee
- User cannot exceed profile → packets will get dropped
- Core router → Simple forwarding: if packet marked as EF, put in priority queue
  - EF packets are forwarded with minimal delay and loss (up to the capacity of the router)

20

---

---

---

---

---

---

---

---

## Assured Forwarding

- AF defines 4 classes
  - Strong assurance for traffic within profile & allow source to exceed profile
    - Implement services that differ relative to each other (e.g., gold service, silver service...)
  - Within each class, there are at least two drop priorities
    - Traffic unlikely to be dropped if user maintains profile
- User and network agree to some traffic profile
  - Edges mark packets up to allowed rate as "in-profile" or high priority
  - Other packets are marked with lower "out-of-profile" priority
  - A congested router drops lower priority packets with a lot higher probability
    - Implemented using RED based priority queuing

21

---

---

---

---

---

---

---

---

## Traffic Conditioning: At Customer Edge

AF traffic (two classes)

EF traffic

22

---

---

---

---

---

---

---

---

## Edge Router Policing: At ISP Edge

23

---

---

---

---

---

---

---

---

## Router Output Processing

Strict high priority used

24

---

---

---

---
