

Tree-Structured Indexes

Chapter 9

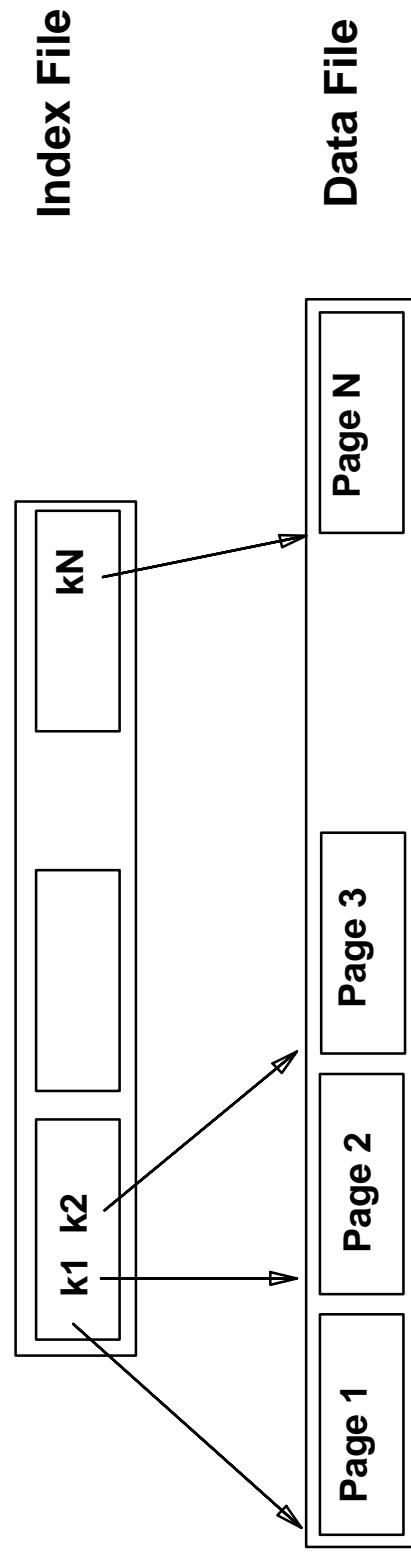

Introduction

- ❖ As for any index, 3 alternatives for data entries k^* :
 - ① Data record with key value k
 - ② $\langle k, \text{rid of data record with search key value } k \rangle$
 - ③ $\langle k, \text{list of rids of data records with search key } k \rangle$
- ❖ Choice is orthogonal to the *indexing technique* used to locate data entries k^* .
- ❖ Tree-structured indexing techniques support both *range searches* and *equality searches*.
- ❖ ISAM: static structure; B+ tree: dynamic, adjusts gracefully under inserts and deletes.

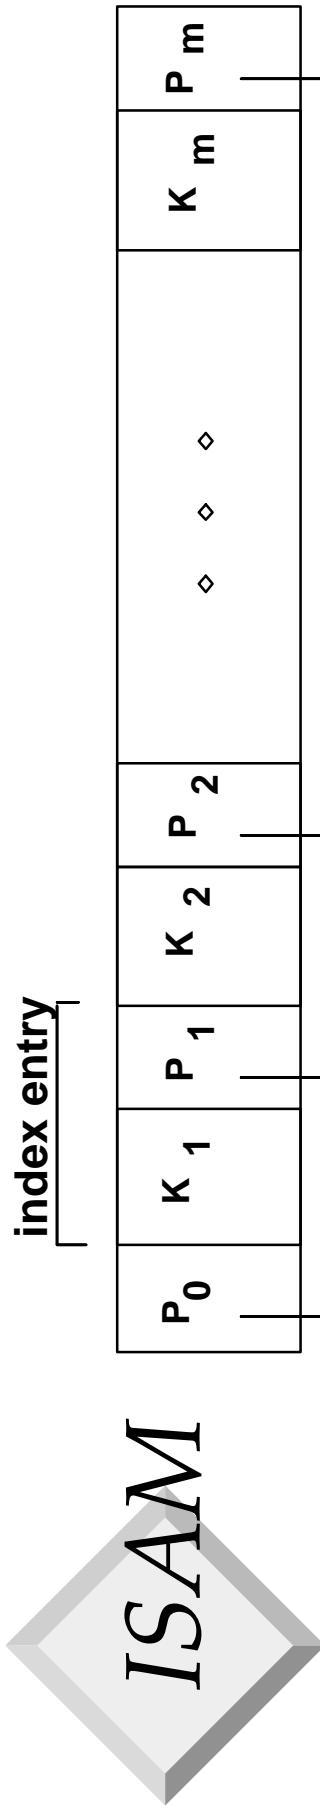

Range Searches

❖ “Find all students with $gpa > 3.0$ ”

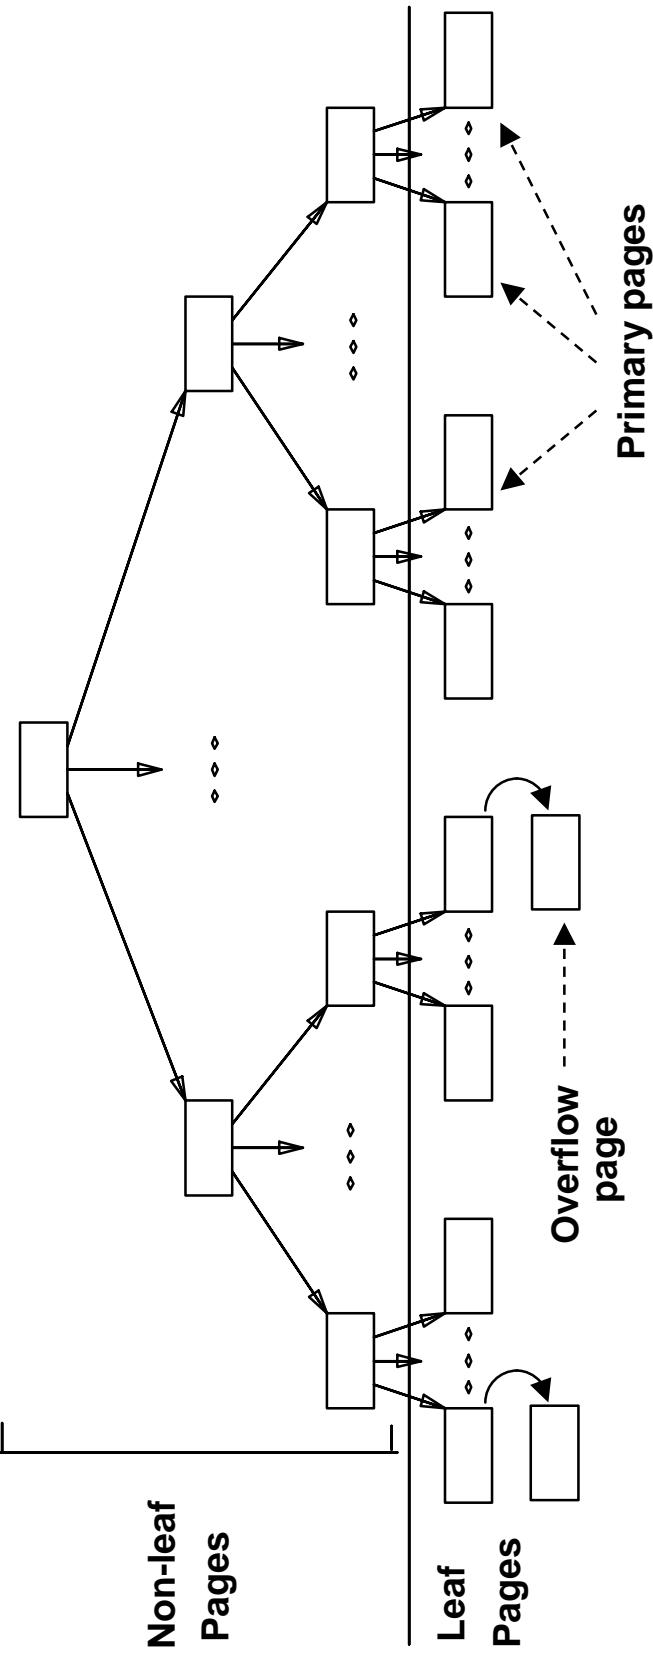

- If data is in sorted file, do binary search to find first such student, then scan to find others.
- Cost of binary search can be quite high.
- ❖ Simple idea: Create an ‘index’ file.

☞ Can do binary search on (smaller) index file!

- ❖ Index file may still be quite large. But we can apply the idea repeatedly!

☞ Leaf pages contain data entries.

Comments on ISAM

Data Pages

Index Pages

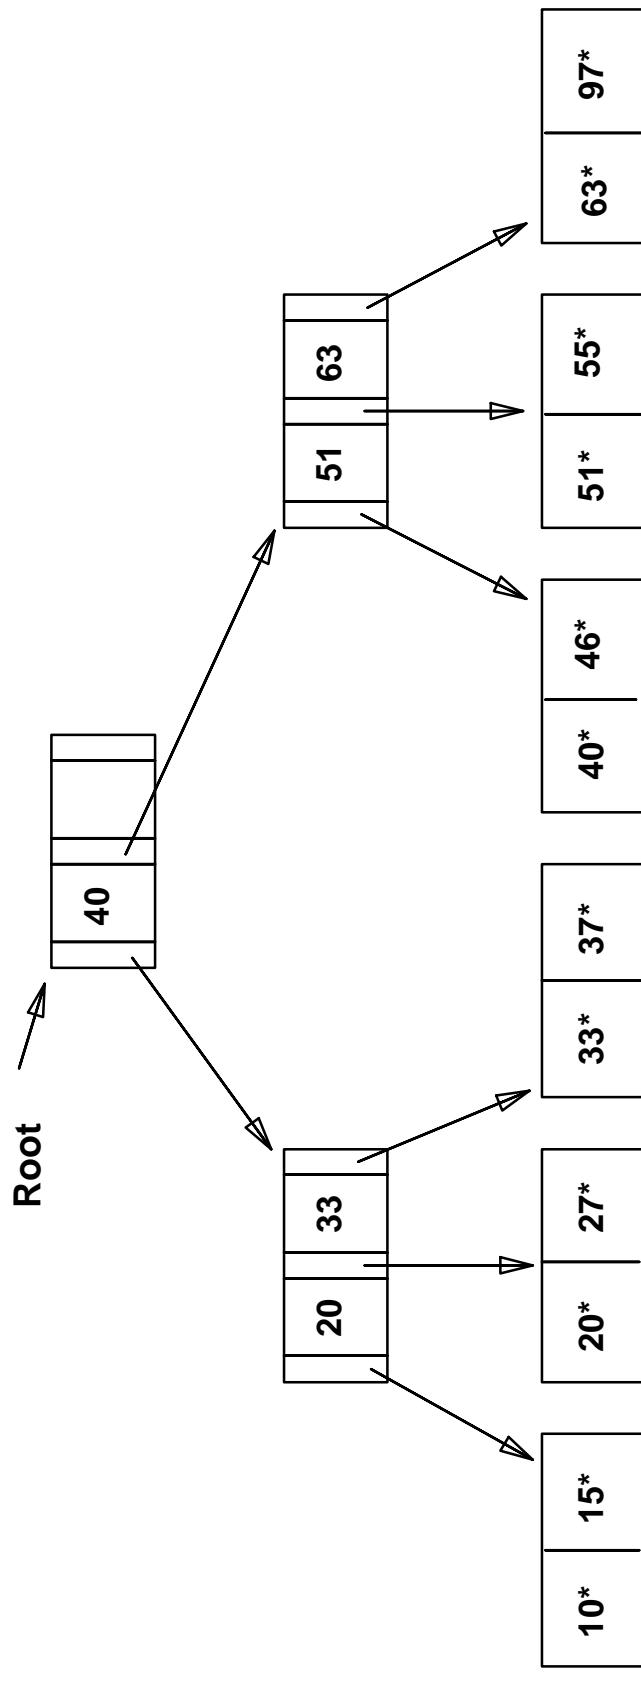

Overflow pages

- ❖ *File creation:* Leaf (data) pages allocated sequentially, sorted by search key; then index pages allocated, then space for overflow pages.
- ❖ *Index entries:* <search key value, page id>; they ‘direct’ search for *data entries*, which are in leaf pages.
- ❖ *Search:* Start at root; use key comparisons to go to leaf.
 $\text{Cost} \propto \log_F N$; $F = \# \text{ entries/index pg}$, $N = \# \text{ leaf pgs}$
- ❖ *Insert:* Find leaf data entry belongs to, and put it there.
- ❖ *Delete:* Find and remove from leaf; if empty overflow page, de-allocate.

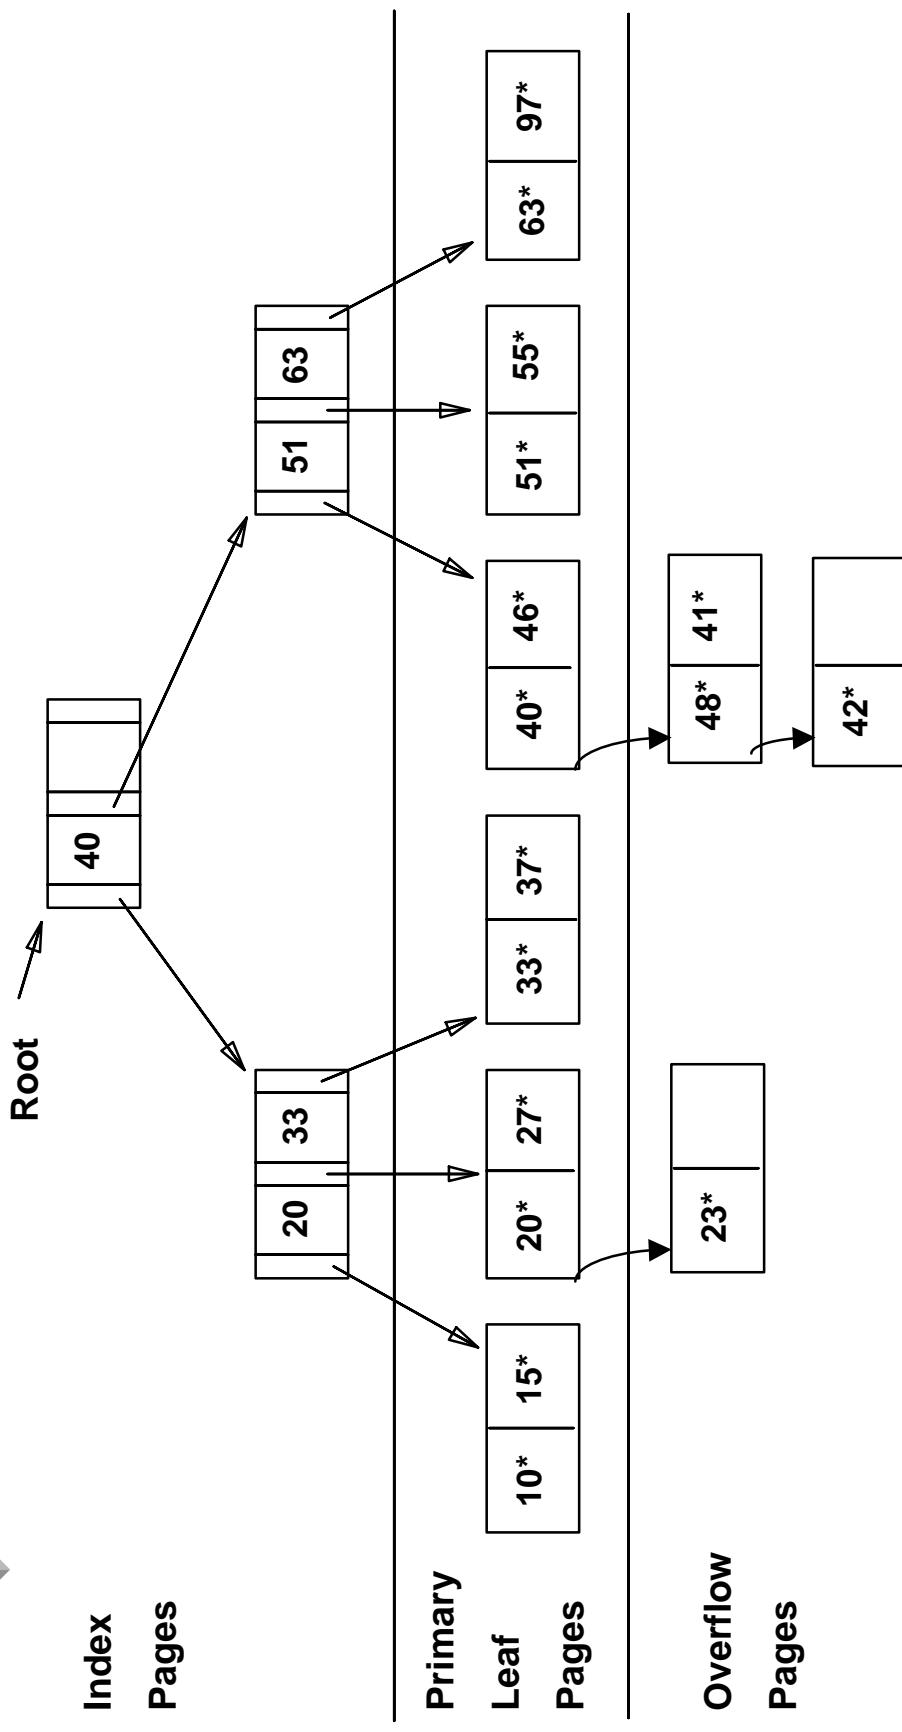

☞ **Static tree structure:** *inserts/deletes affect only leaf pages.*

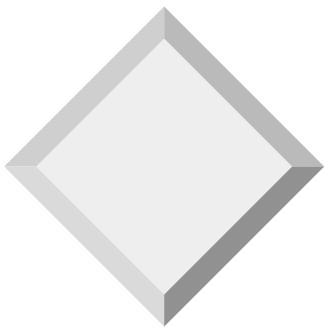

Example ISAM Tree

- ❖ Each node can hold 2 entries; no need for ‘next-page’ pointers. (Why?)

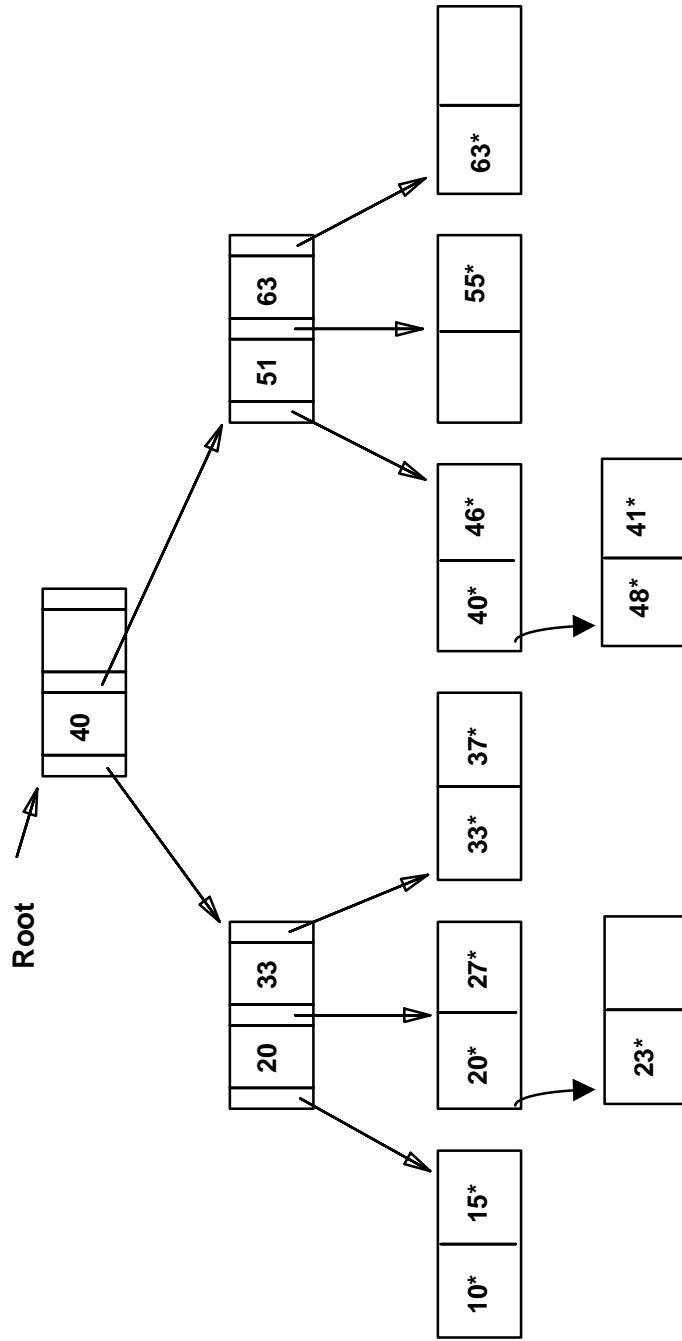

After Inserting 23, 48*, 41*, 42* ...*

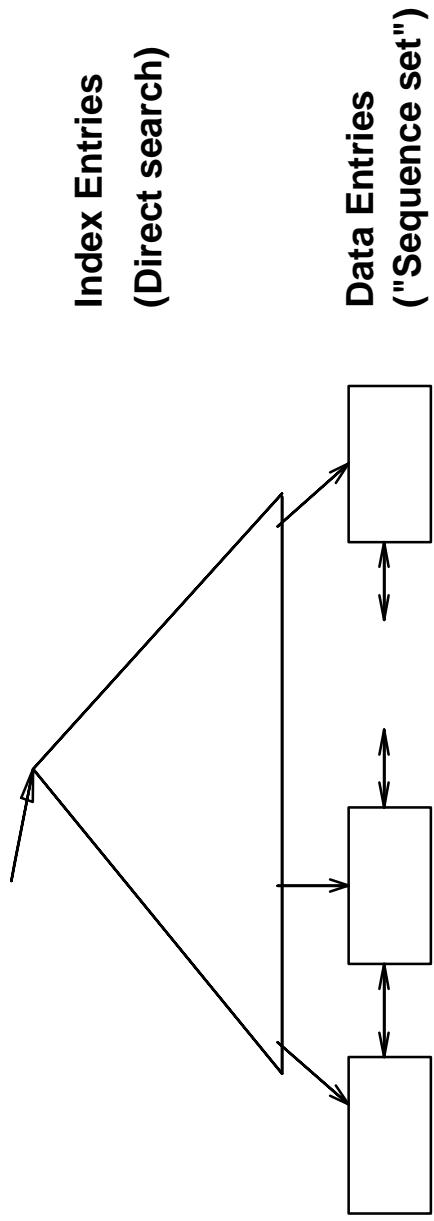

... Then Deleting 42^* , 51^* , 97^*

☞ Note that 51^* appears in index levels, but not in leaf!

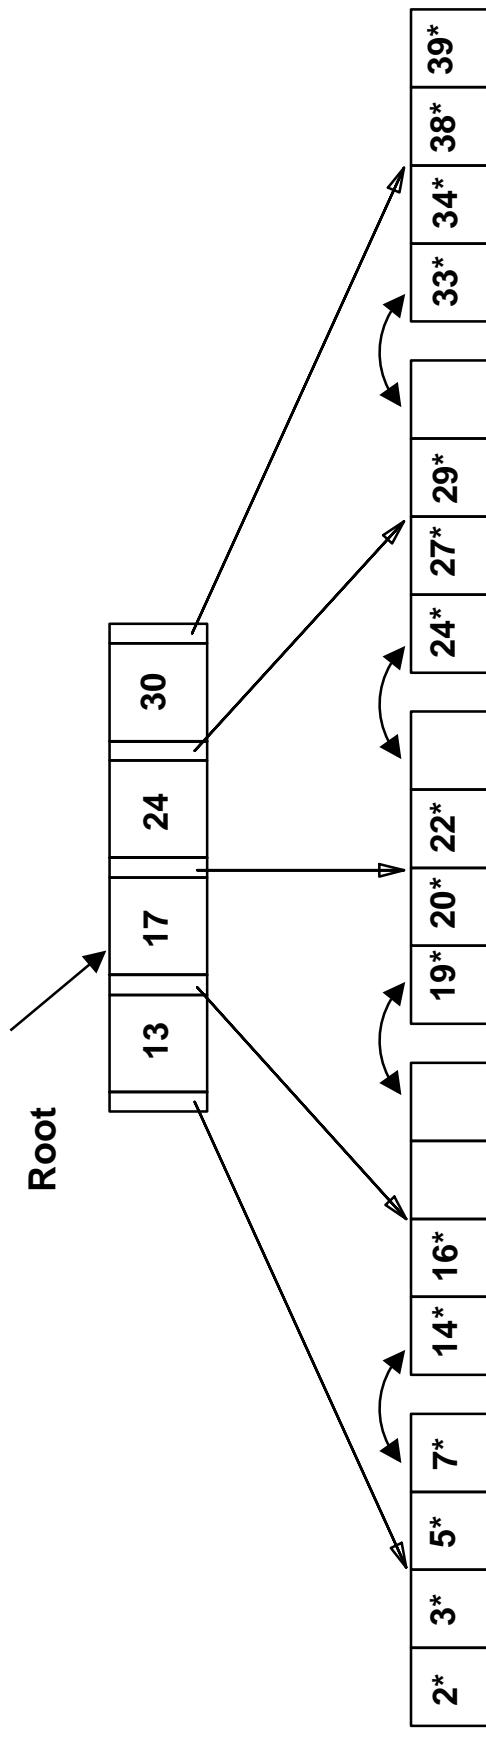

B+ Tree: The Most Widely Used Index

- ❖ Insert/delete at $\log_F N$ cost; keep tree *height-balanced*. ($F = \text{fanout}$, $N = \# \text{ leaf pages}$)
- ❖ Minimum 50% occupancy (except for root). Each node contains $d \leq n \leq 2d$ entries. The parameter d is called the *order* of the tree.
- ❖ Supports equality and range-searches efficiently.

Example B+ Tree

- ❖ Search begins at root, and key comparisons direct it to a leaf (as in ISAM).
- ❖ Search for 5^* , 15^* , all data entries $\geq 24^*$...

☞ Based on the search for 15^* , we know it is not in the tree!

B+ Trees in Practice

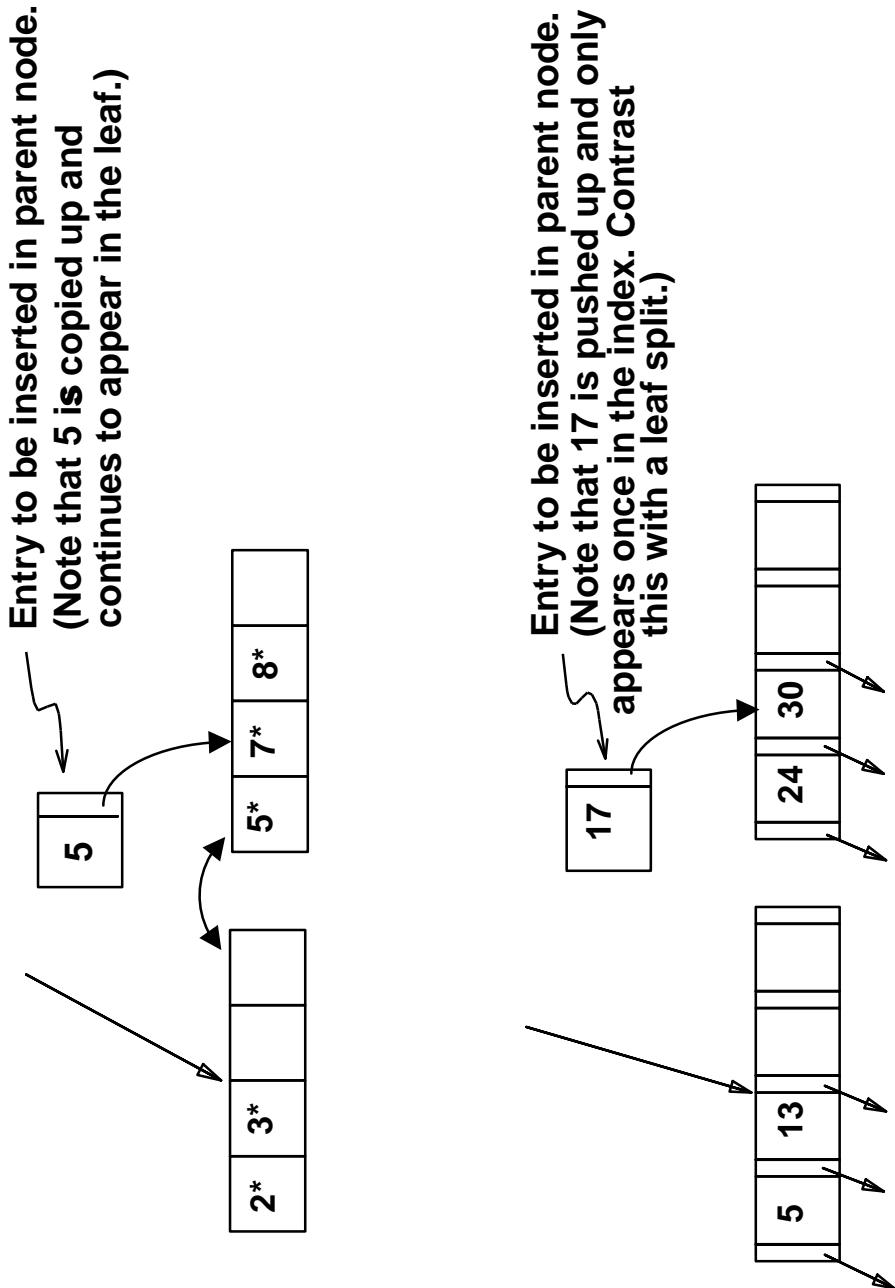

- ❖ Typical order: 100. Typical fill-factor: 67%.
 - average fanout = 133
- ❖ Typical capacities:
 - Height 4: $133^4 = 312,900,700$ records
 - Height 3: $133^3 = 2,352,637$ records
- ❖ Can often hold top levels in buffer pool:
 - Level 1 = 1 page = 8 Kbytes
 - Level 2 = 133 pages = 1 Mbyte
 - Level 3 = 17,689 pages = 133 MBytes

Inserting a Data Entry into a B+ Tree

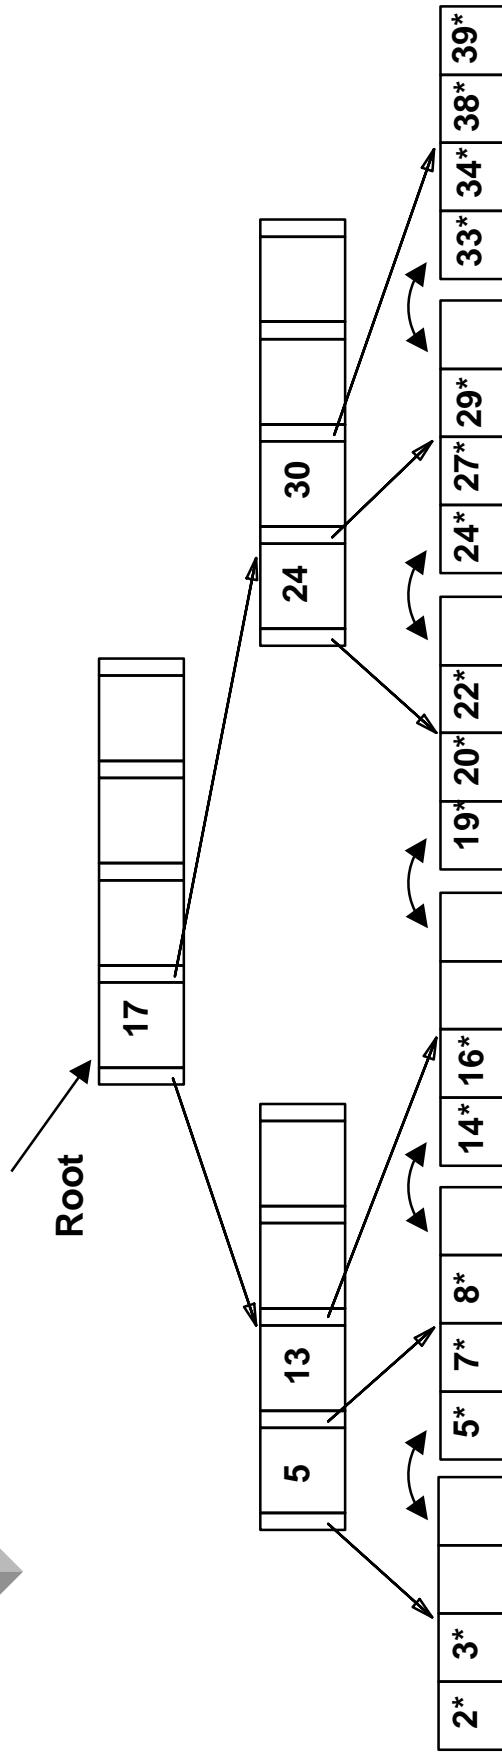

- ❖ Find correct leaf L .
- ❖ Put data entry onto L .
 - If L has enough space, done!
 - Else, must split L (*into L and a new node L2*)
 - ◆ Redistribute entries evenly, copy up middle key.
 - ◆ Insert index entry pointing to $L2$ into parent of L .
- ❖ This can happen recursively
 - To split index node, redistribute entries evenly, but push up middle key. (Contrast with leaf splits.)
- ❖ Splits “grow” tree; root split increases height.
 - Tree growth: gets wider or one level taller at top.

Inserting 8* into Example B+ Tree

- ❖ Observe how minimum occupancy is guaranteed in both leaf and index pg splits.
- ❖ Note difference between *copy-up* and *push-up*; be sure you understand the reasons for this.

Example B+ Tree After Inserting 8*

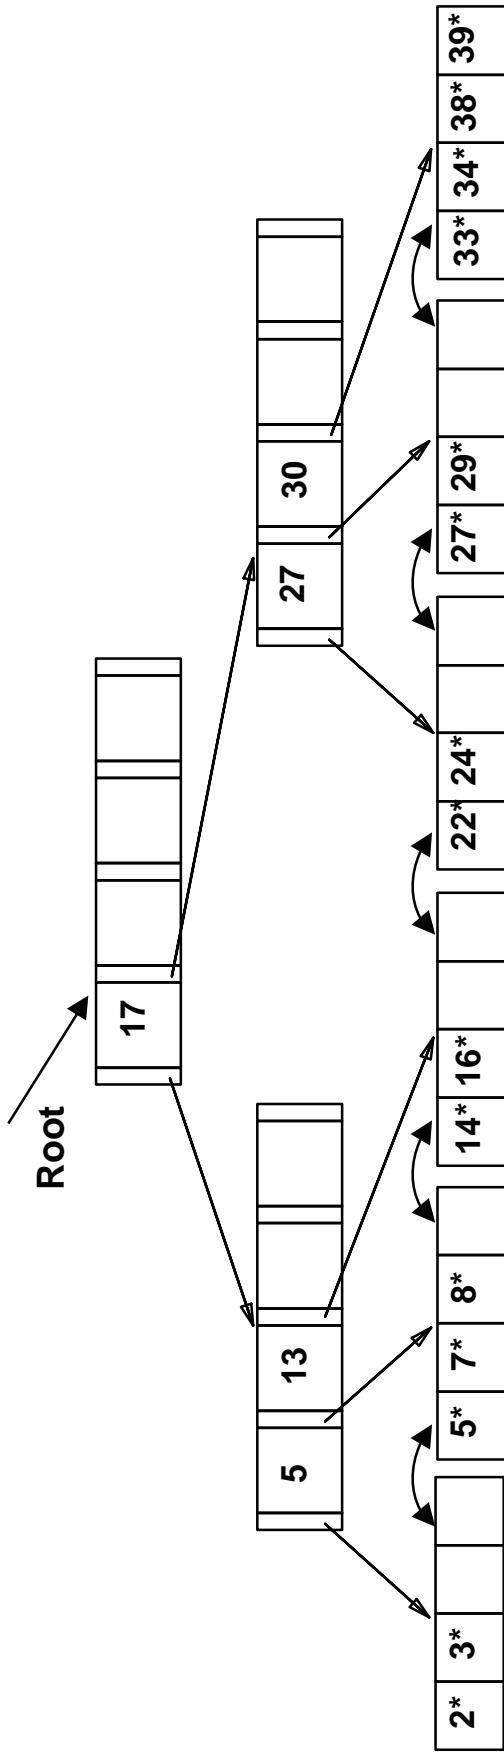

- ❖ Notice that root was split, leading to increase in height.
- ❖ In this example, we can avoid split by re-distributing entries; however, this is usually not done in practice.

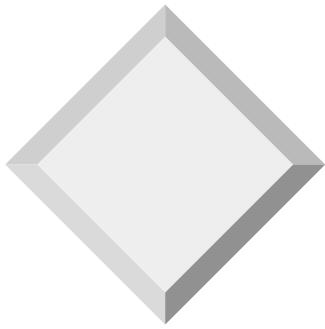

Deleting a Data Entry from a B+ Tree

- ❖ Start at root, find leaf L where entry belongs.
- ❖ Remove the entry.
 - If L is at least half-full, *done!*
 - If L has only $d-1$ entries,
 - ◆ Try to re-distribute, borrowing from sibling (*adjacent node with same parent as L*).
 - ◆ If re-distribution fails, merge L and sibling.
- ❖ If merge occurred, must delete entry (pointing to L or sibling) from parent of L .
- ❖ Merge could propagate to root, decreasing height.

Example Tree After (Inserting 8*, Then) Deleting 19* and 20* ...

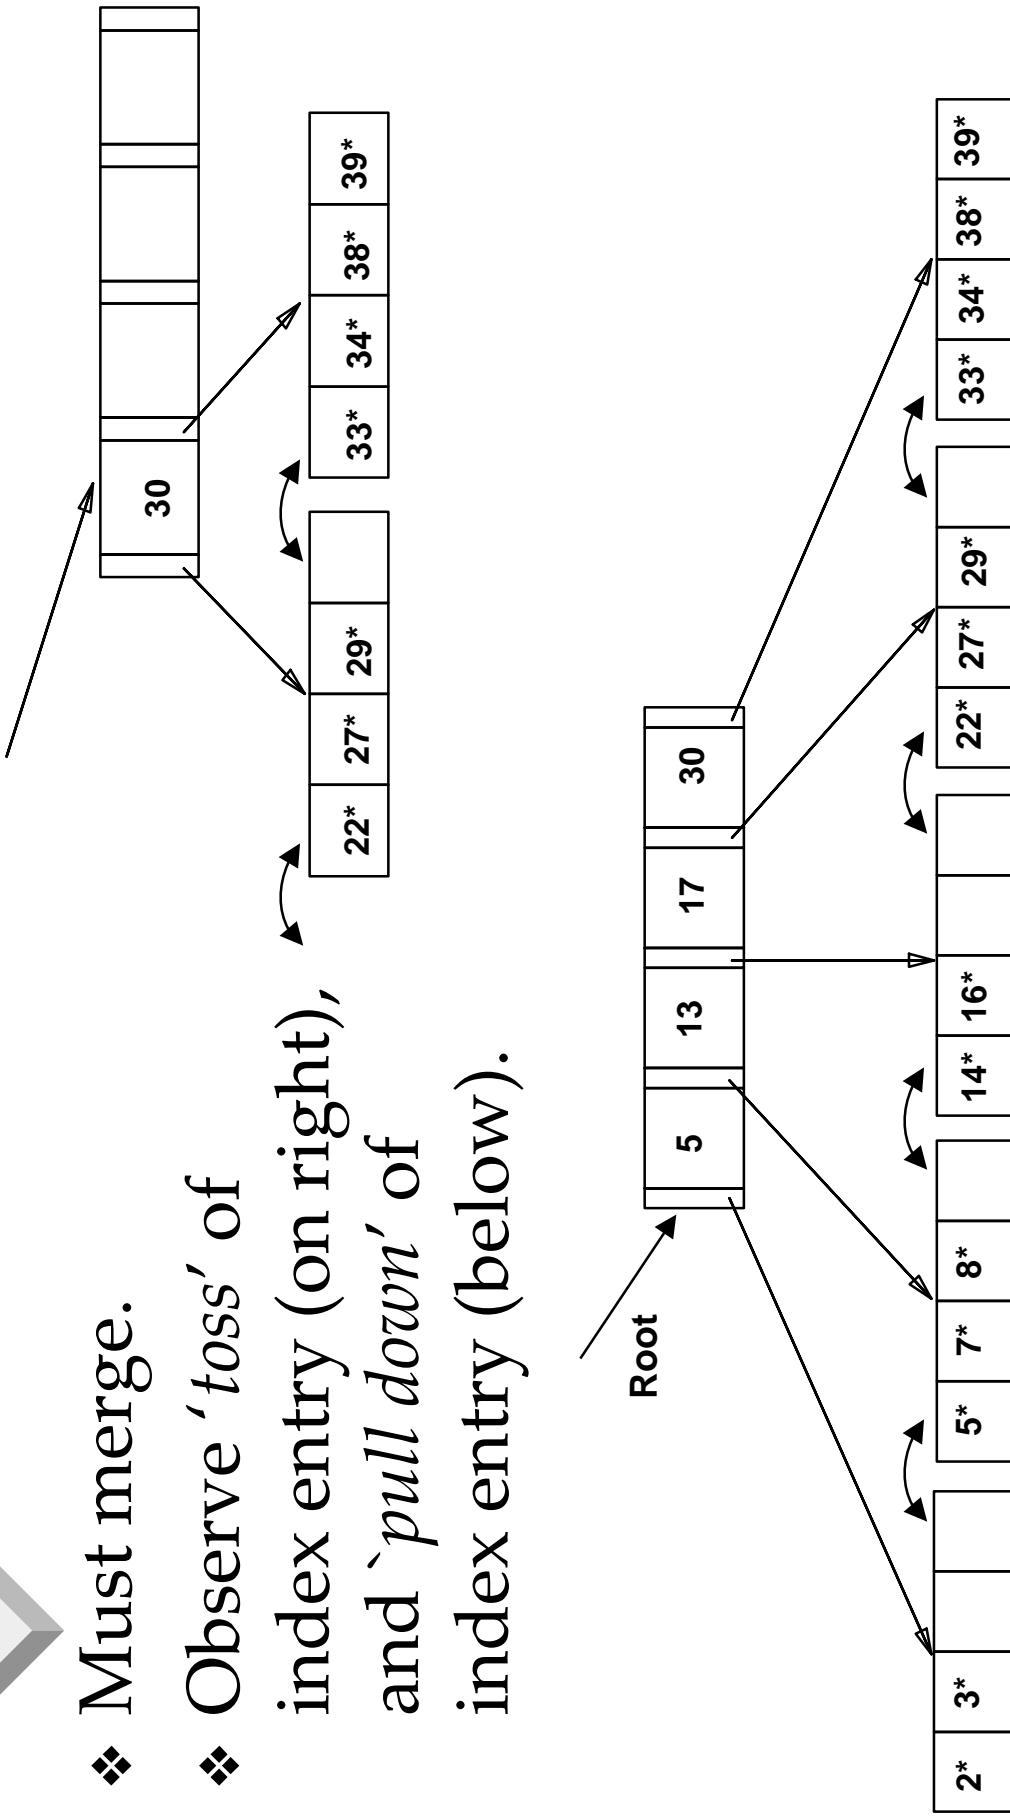

- ❖ Deleting 19* is easy.
- ❖ Deleting 20* is done with re-distribution.
Notice how middle key is copied up.

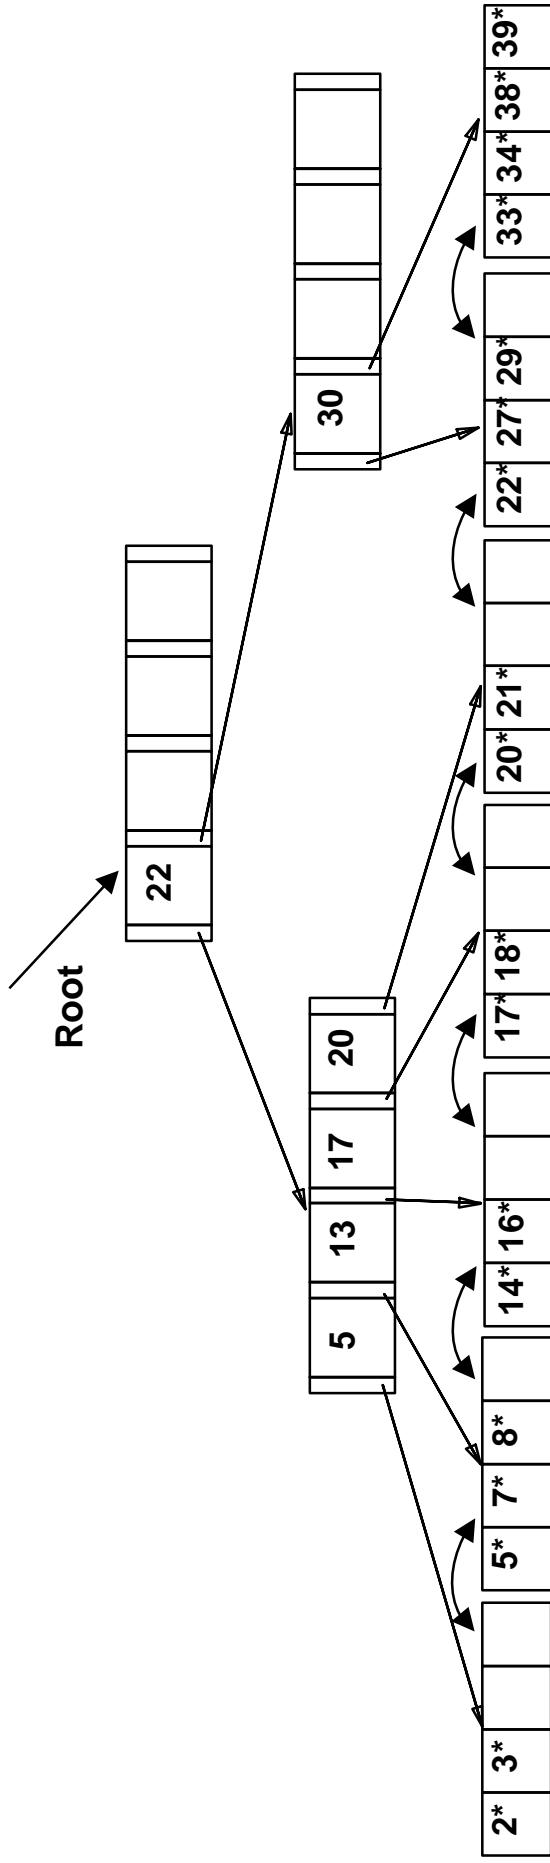

... And Then Deleting 24*

- ❖ Must merge.
- ❖ Observe 'toss' of index entry (on right), and 'pull down' of index entry (below).

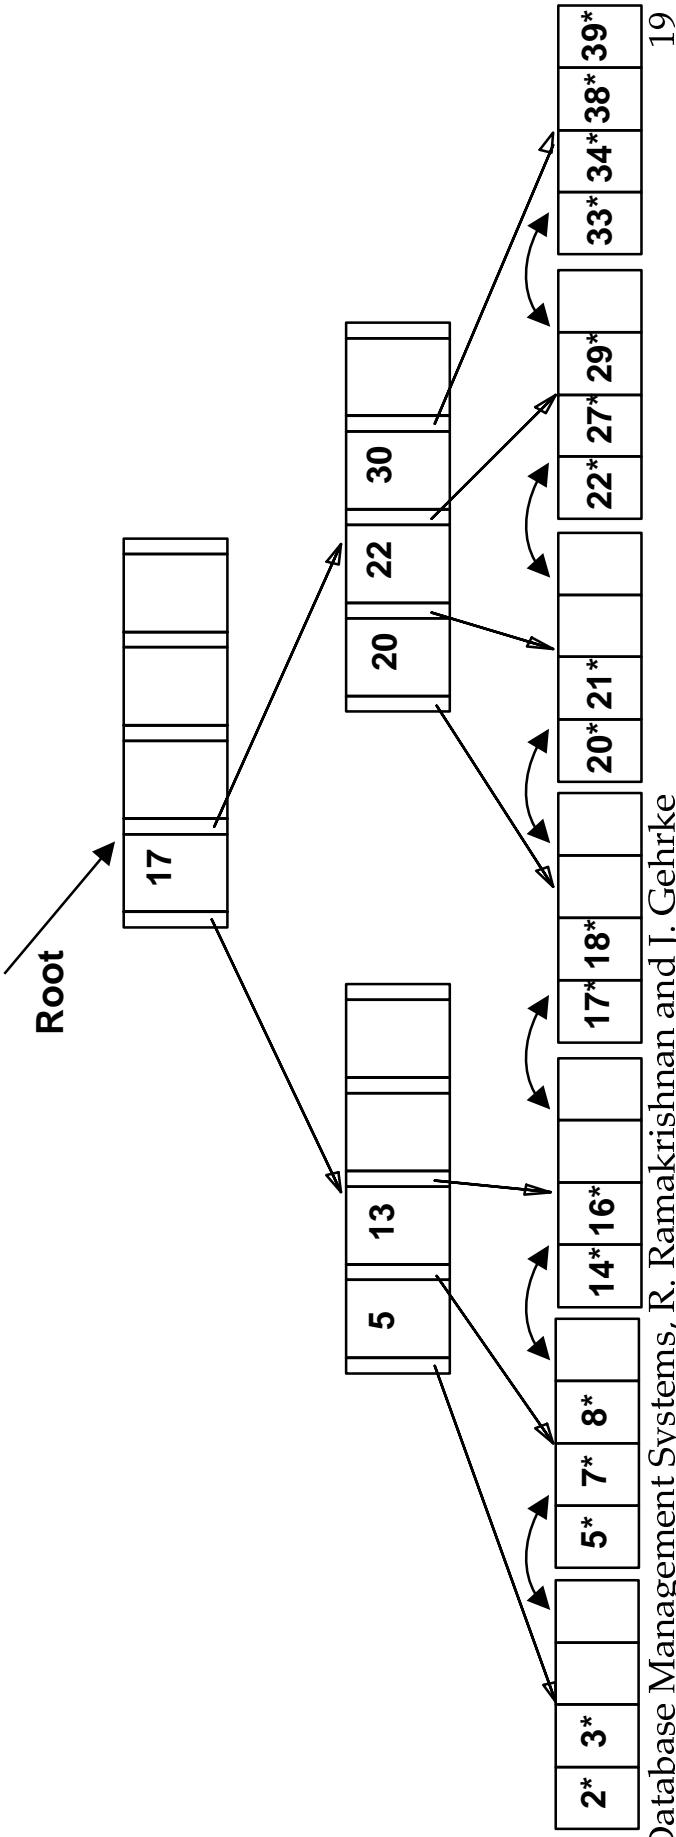

Example of Non-leaf Re-distribution

- ❖ Tree is shown below *during deletion* of 24*. (What could be a possible initial tree?)
- ❖ In contrast to previous example, can re-distribute entry from left child of root to right child.

After Re-distribution

- ❖ Intuitively, entries are re-distributed by ‘pushing through’ the splitting entry in the parent node.
- ❖ It suffices to re-distribute index entry with key 20; we’ve re-distributed 17 as well for illustration.

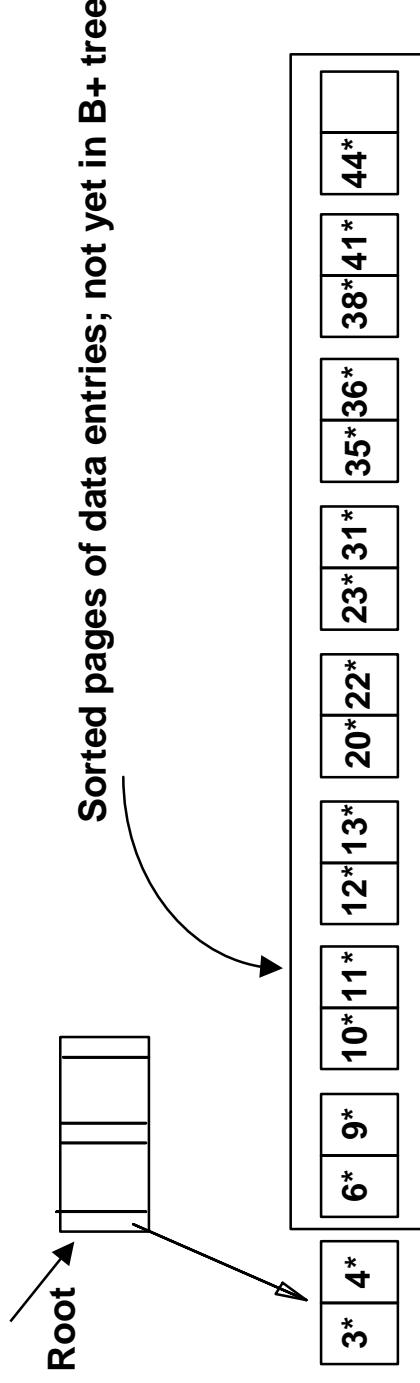

Prefix Key Compression

- ❖ Important to increase fan-out. (Why?)
- ❖ Key values in index entries only ‘direct traffic’;
can often compress them.
 - E.g., If we have adjacent index entries with search key values *Dannon Yogurt*, *David Smith* and *Devarakonda Murthy*, we can abbreviate *David Smith* to *Dav*. (The other keys can be compressed too ...)
 - ◆ Is this correct? Not quite! What if there is a data entry *Davey Jones*? (Can only compress *David Smith* to *Davi*)
 - ◆ In general, while compressing, must leave each index entry greater than every key value (in any subtree) to its left.
- ❖ Insert / delete must be suitably modified.

Bulk Loading of a B+ Tree

- ❖ If we have a large collection of records, and we want to create a B+ tree on some field, doing so by repeatedly inserting records is very slow.
- ❖ Bulk Loading can be done much more efficiently.
- ❖ *Initialization:* Sort all data entries, insert pointer to first (leaf) page in a new (root) page.

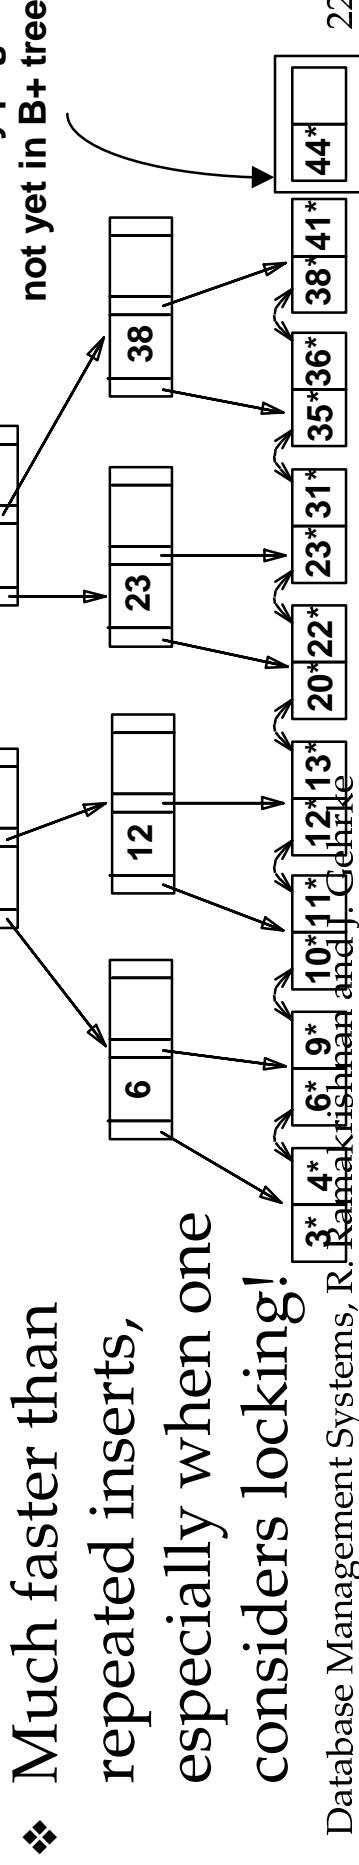

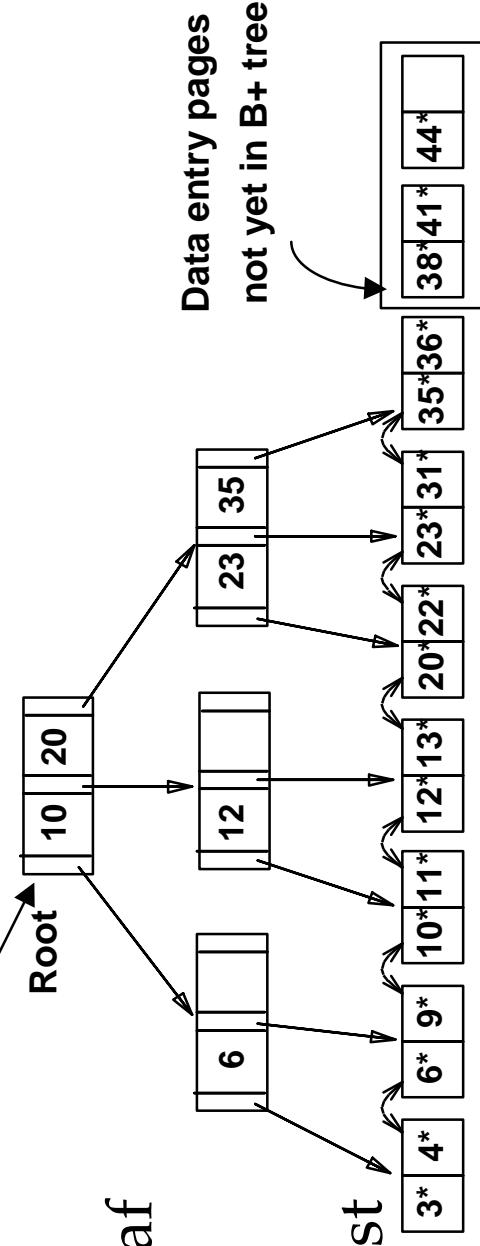

Bulk Loading (Contd.)

- ❖ Index entries for leaf

pages always entered into right-most index page just above leaf level.

When this fills up, it splits. (Split may go up right-most path to the root.)

Summary of Bulk Loading

- ❖ Option 1: multiple inserts.
 - Slow.
 - Does not give sequential storage of leaves.
- ❖ Option 2: Bulk Loading
 - Has advantages for concurrency control.
 - Fewer I/Os during build.
 - Leaves will be stored sequentially (and linked, of course).
 - Can control “fill factor” on pages.

A Note on ‘Order’

- ❖ *Order (d)* concept replaced by physical space criterion in practice (*‘at least half-full’*).
 - Index pages can typically hold many more entries than leaf pages.
 - Variable sized records and search keys mean different nodes will contain different numbers of entries.
 - Even with fixed length fields, multiple records with the same search key value (*duplicates*) can lead to variable-sized data entries (if we use Alternative (3)).

Summary

- ❖ Tree-structured indexes are ideal for range-searches, also good for equality searches.
- ❖ ISAM is a static structure.
 - Only leaf pages modified; overflow pages needed.
 - Overflow chains can degrade performance unless size of data set and data distribution stay constant.
- ❖ B+ tree is a dynamic structure.
 - Inserts / deletes leave tree height-balanced; $\log_F N$ cost.
 - High fanout (F) means depth rarely more than 3 or 4.
 - Almost always better than maintaining a sorted file.

Summary (Contd.)

- Typically, 67% occupancy on average.
- Usually preferable to ISAM, modulo *locking* considerations; adjusts to growth gracefully.
 - If data entries are data records, splits can change rids!
- ❖ Key compression increases fanout, reduces height.
- ❖ Bulk loading can be much faster than repeated inserts for creating a B+ tree on a large data set.
- ❖ Most widely used index in database management systems because of its versatility. One of the most optimized components of a DBMS.
