CS540 Uninformed Search

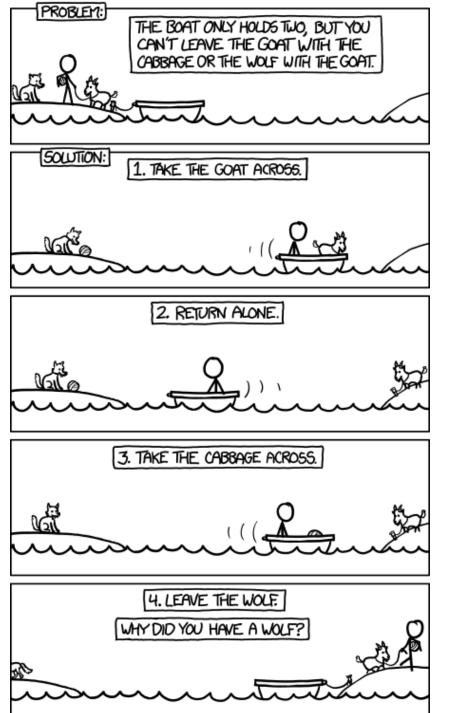

Xiaojin Zhu

jerryzhu@cs.wisc.edu Computer Sciences Department University of Wisconsin, Madison

Main messages

- Many AI problems can be formulated as search.
- Iterative deepening is good when you don't know much.

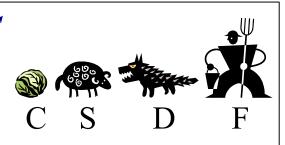

http://xkcd.com/1134/

The search problem

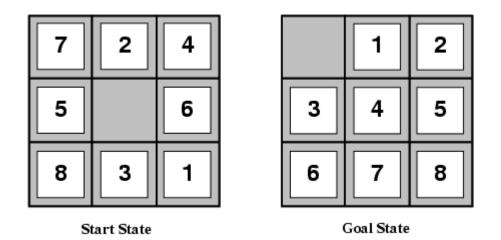

- State space *S* : all valid configurations
- Initial states (nodes) $I = \{(CSDF,)\} \subseteq S$
 - Where's the boat?
- Goal states $G = \{(, CSDF)\} \subseteq S$

- Successor function *succs*(s)⊆ S : states reachable in one step (one arc) from s
 - succs((CSDF,)) = {(CD, SF)}
 - succs((CDF,S)) = {(CD,FS), (D,CFS), (C, DFS)}
- **Cost**(s,s')=1 for all arcs. (weighted later)
- The search problem: find a solution path from a state in *I* to a state in *G*.
 - Optionally minimize the cost of the solution.

Search examples

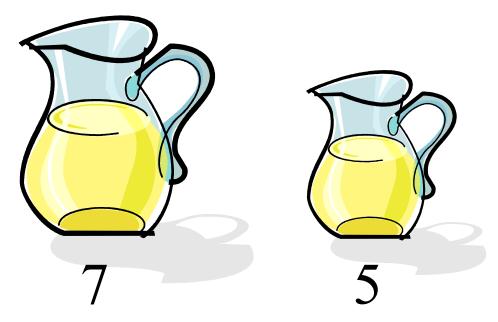

• 8-puzzle

- States = configurations
- successor function = up to 4 kinds of movement
- Cost = 1 for each move

Search examples

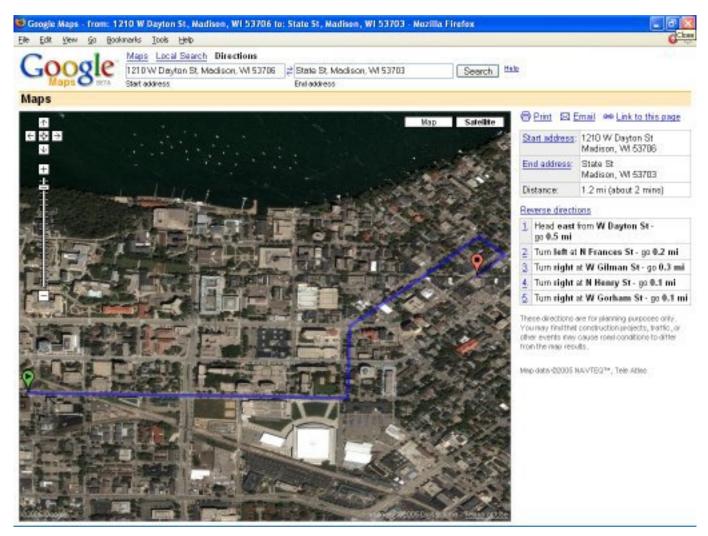

• Water jugs: how to get 1?

- Goal? (How many goal states?)
- Successor function: fill up (from tap or other jug), empty (to ground or other jug)

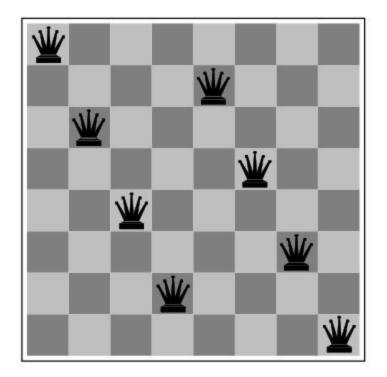

Search examples

Route finding (state? Successors? Cost weighted)

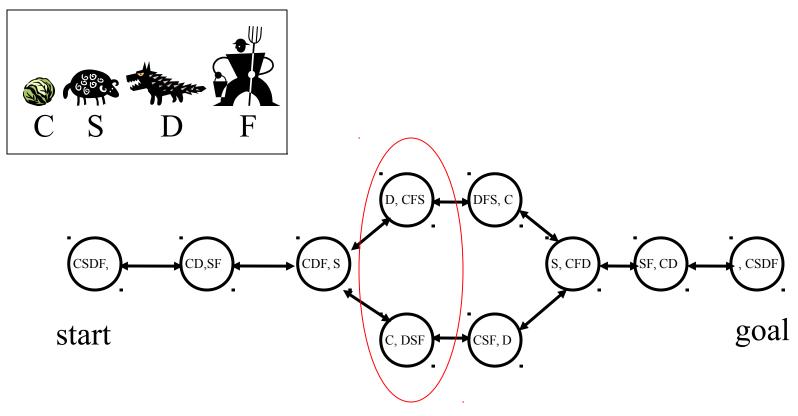

8-queens

• State: complete configuration vs. column-by-column

• Tree instead of graph

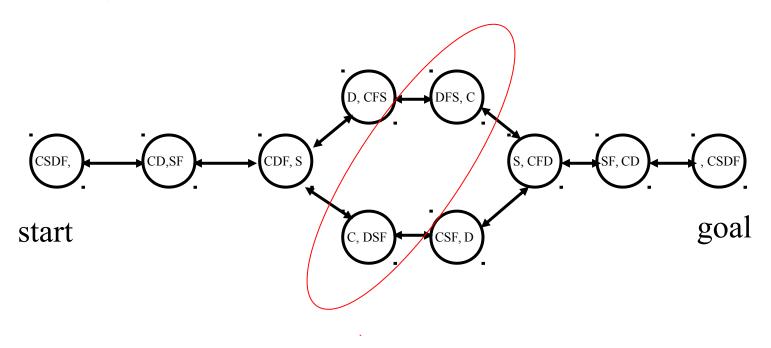

A directed graph in state space

- In general there will be many generated, but unexpanded states at any given time
- One has to choose which one to expand next

Different search strategies

- The generated, but not yet expanded states form the fringe (OPEN).
- The essential difference is which one to expand first.
- Deep or shallow?

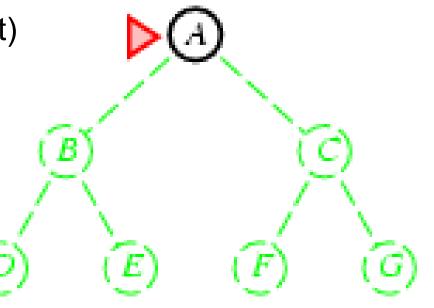

Uninformed search on trees

- Uninformed means we only know:
 - The goal test
 - The *succs*() function
- But not which non-goal states are better: that would be informed search (next lecture).
- For now, we also assume *succs*() graph is a tree.
 - Won't encounter repeated states.
 - We will relax it later.
- Search strategies: BFS, UCS, DFS, IDS, BIBFS
- Differ by what un-expanded nodes to expand

Expand the shallowest node first

- Examine states **one** step away from the initial states
- Examine states **two** steps away from the initial states
- and so on... ripple Start

Use a queue (First-in First-out) 1. en_queue(Initial states) 2. While (queue not empty) 3. s = de_queue() 4. if (s==goal) success! 5. T = succs(s) 6. en_queue(T) 7. endWhile

Use a queue (First-in First-out) 1. en queue(Initial states) 2. While (queue not empty) 3. s = de queue()4. if (s==goal) success! **5.** T = succs(s)6. en_queue(T) 7. endWhile

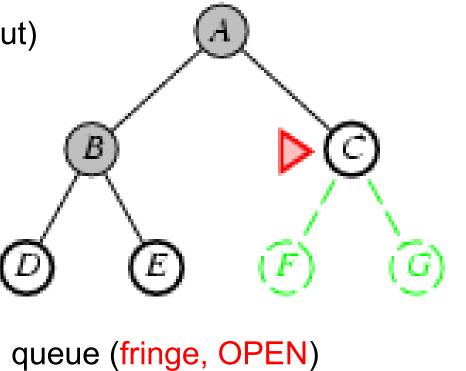

(B) (E) (F) (G)

queue (fringe, OPEN) \rightarrow [A] \rightarrow

Use a queue (First-in First-out) 1. en queue(Initial states) 2. While (queue not empty) **3.** s = de_queue() 4. if (s==goal) success! **5.** T = succs(s)6. en_queue(T) 7. endWhile

queue (fringe, OPEN) \rightarrow [CB] \rightarrow A

Use a queue (First-in First-out) 1. en queue(Initial states) 2. While (queue not empty) **3.** s = de_queue() 4. if (s==goal) success! **5.** T = succs(s)6. en_queue(T) 7. endWhile \rightarrow [EDC] \rightarrow B

slide 17

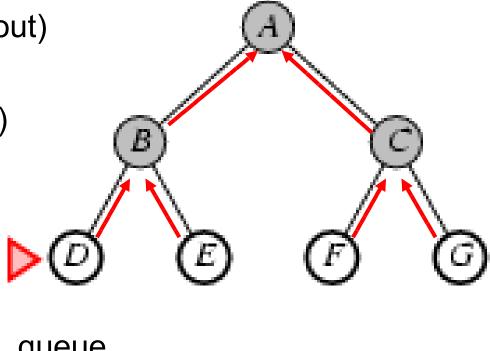

Use a queue (First-in First-out) 1. en queue(Initial states) 2. While (queue not empty) **3.** s = de_queue() 4. if (s==goal) success! **5.** T = succs(s)6. en_queue(T) 7. endWhile queue (fringe, OPEN) \rightarrow [GFED] \rightarrow C

If G is a goal, we've seen it, but we don't stop!

Use a queue (First-in First-out)

- en_queue(Initial states)
- While (queue not empty)
- s = de_queue()
- if (s==goal) success!
- T = succs(s)
- for t in T: t.prev=s
- en_queue(T)
- endWhile

Looking stupid? Indeed. But let's be consistent...

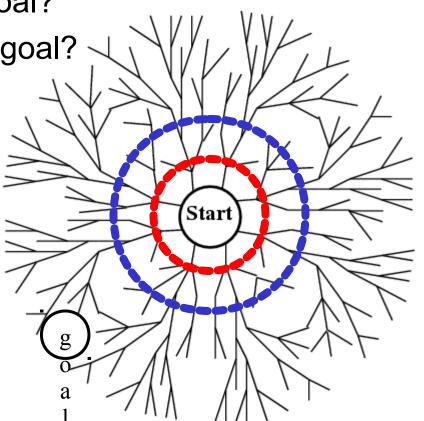

queue →[] →G

... until much later we pop G.

We need back pointers to recover the solution path.

Performance of BFS

- Assume:
 - the graph may be infinite.
 - Goal(s) exists and is only finite steps away.
- Will BFS find at least one goal?
- Will BFS find the least cost goal?
- Time complexity?
 - # states generated
 - Goal d edges away
 - Branching factor b
- Space complexity?
 - # states stored

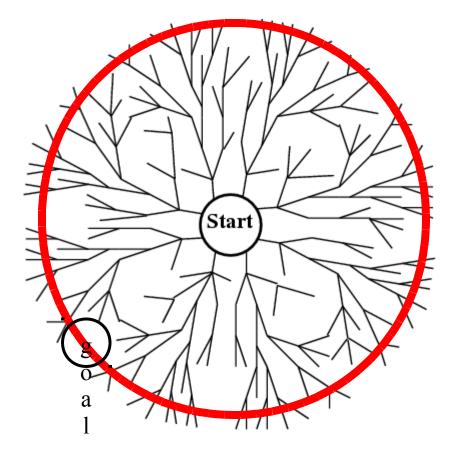

Performance of BFS

Four measures of search algorithms:

- Completeness (not finding all goals): yes, BFS will find a goal.
- Optimality: yes if edges cost 1 (more generally positive non-decreasing in depth), no otherwise.
- Time complexity (worst case): goal is the last node at radius *d*.
 - Have to generate all nodes at radius d.
 - $b + b^2 + ... + b^d \sim O(b^d)$
- Space complexity (bad)
 - Back pointers for all generated nodes O(b^d)
 - The queue / fringe (smaller, but still O(b^d))

What's in the fringe (queue) for BFS?

• Convince yourself this is *O*(*b*^{*d*})

Performance of search algorithms on trees

b: branching factor (assume finite) d: goal depth

	Complete	optimal	time	space
Breadth-first search	Y	Y, if ¹	O(bď)	O(b ^d)

1. Edge cost constant, or positive non-decreasing in depth

Performance of BFS

Four measures of search algorithms:

 Completeness (not finding all goals): find a goal. Solution: Uniform-cost search

- Optimality: yes if edges cost 1 (more generally positive non-decreasing with depth), no otherwise.
- Time complexity (worst case): goal is the last node at radius *d*.
 - Have to generate all nodes at radius d.
 - $b + b^2 + ... + b^d \sim O(b^d)$
- Space complexity (bad, Figure 3.11)
 - Back points for all generated nodes O(b^d)
 - The queue (smaller, but still O(b^d))

Uniform-cost search

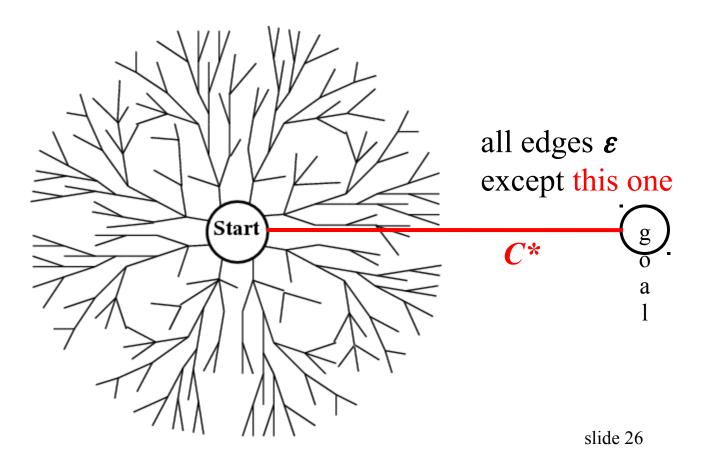

- Find the least-cost goal
- Each node has a path cost from start (= sum of edge costs along the path). Expand the least cost node first.
- Use a priority queue instead of a normal queue
 - Always take out the least cost item
 - Remember *heap*? time O(log(#items in heap))

That's it*

* Complications on graphs (instead of trees). Later.

Uniform-cost search (UCS)

- Complete and optimal (if edge costs $\geq \epsilon > 0$)
- Time and space: can be much worse than BFS
 - Let C* be the cost of the least-cost goal
 - $O(b^{C^{*/\varepsilon}})$, possibly $C^{*/\varepsilon} >> d$

Performance of search algorithms on trees

b: branching factor (assume finite) d: goal depth

	Complete	optimal	time	space
Breadth-first search	Y	Y, if ¹	O(bď)	O(bď)
Uniform-cost search ²	Y	Y	O(b ^{C*/ε})	O(b ^{C*/ε})

- 1. edge cost constant, or positive non-decreasing in depth
- edge costs $\geq \epsilon > 0$. C* is the best goal path cost.

General State-Space Search Algorithm

function general-search(problem, QUEUEING-FUNCTION)

- ;; problem describes the start state, operators, goal test, and
- ;; operator costs
- ;; queueing-function is a comparator function that ranks two states
- ;; general-search returns either a goal node or "failure"

nodes = MAKE-QUEUE(MAKE-NODE(problem.INITIAL-STATE)) loop

- if EMPTY(nodes) then return "failure"
- node = REMOVE-FRONT(nodes)
- if problem.GOAL-TEST(node.STATE) succeeds

then return node

- nodes = **QUEUEING-FUNCTION**(nodes, **EXPAND**(node, problem.OPERATORS))
- ;; succ(s)=EXPAND(s, OPERATORS)
- ;; Note: The goal test is NOT done when nodes are generated
- ;; Note: This algorithm does not detect loops

end

Recall the bad space complexity of BFS

Four measures of search algorithms:

 Completeness (not finding all goals): find a goal. Solution: Uniform-cost search

- Optimality: yes if edges cost 1 (more generally positive non-decreasing with depth), no otherwise.
- Time comple Solution: radius *d*.
 Have to g
 Solution: Depth-first search
 Solution: bepth-first search
 Solution: bepth-first search
 Solution: bepth-first search

•
$$b + b^2 + ... + b^d \sim O$$

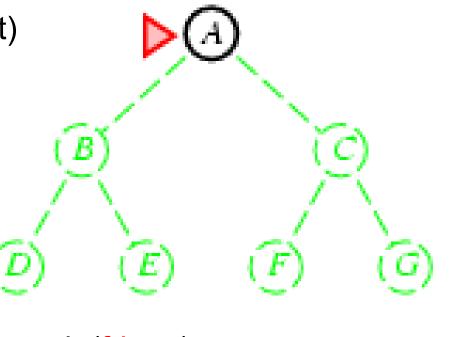

- Space complexity (bad, Figure 3.11)
 - Back points for all generated nodes O(b^d)
 - The queue (smaller, but still O(b^d))

Depth-first search

Expand the deepest node first 1. Select a direction, go deep to the end 2. Slightly change the end **3.** Slightly change the end some more... fan Start

Depth-first search (DFS)

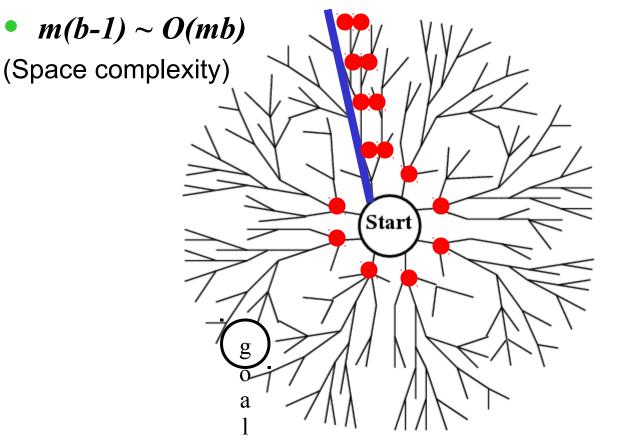

Use a stack (First-in Last-out) **1**. push(Initial states) 2. While (stack not empty) 3. s = pop()4. if (s==goal) success! **5.** T = succs(s)6. push(T) 7. endWhile

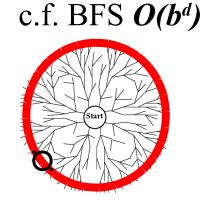

stack (<mark>fringe</mark>) [] ⇔

What's in the fringe for DFS?

m = maximum depth of graph from start

"backtracking search" even less space
 generate siblings (if applicable)

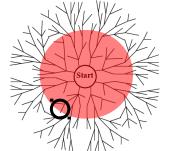

What's wrong with DFS?

Start

- Infinite tree: may _ not find goal (incomplete)
- May not be optimal
- Finite tree: may visit almost all nodes, time complexity O(b^m)

g

Performance of search algorithms on trees

b: branching factor (assume finite) d: goal depth m: graph depth

	Complete	optimal	time	space
Breadth-first search	Y	Y, if ¹	O(bď)	O(b ^d)
Uniform-cost search ²	Y	Y	O(b ^{C*/ε})	O(b ^{C*/} ^ε)
Depth-first search	Ν	Ν	O(b ^m)	O(bm)

1. edge cost constant, or positive non-decreasing in depth

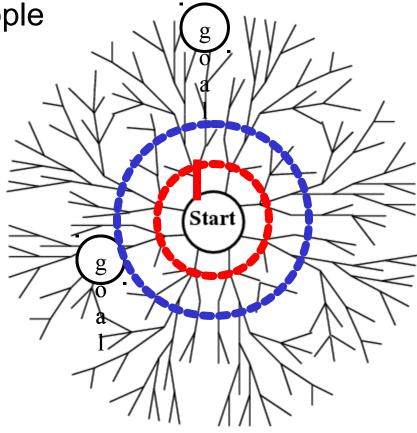

• edge costs $\geq \epsilon > 0$. C* is the best goal path cost.

How about this?

1. DFS, but stop if path length > 1.

2. If goal not found, repeat DFS, stop if path length >2.
3. And so on...

fan within ripple

Iterative deepening

- Search proceeds like BFS, but fringe is like DFS
 - Complete, optimal like BFS
 - Small space complexity like DFS
- A huge waste?
 - Each deepening repeats DFS from the beginning
 - No! $db + (d-1)b^2 + (d-2)b^3 + \dots + b^d \sim O(b^d)$
 - Time complexity like BFS
- Preferred uninformed search method

Performance of search algorithms on trees

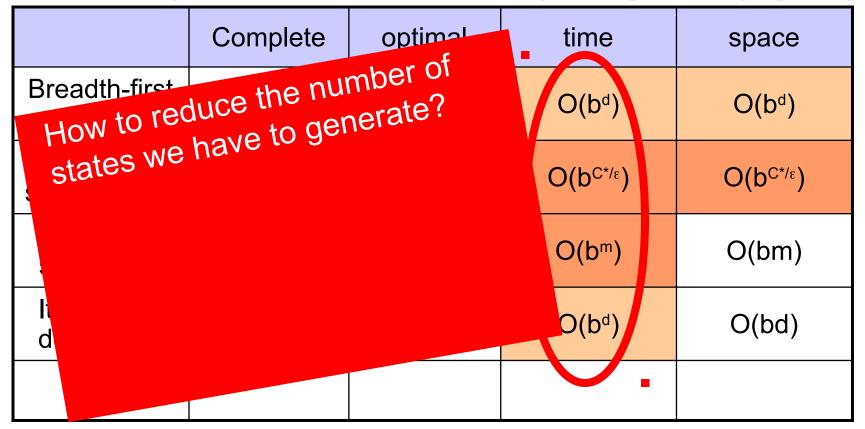

b: branching factor (assume finite) d: goal depth m: graph depth

	Complete	optimal	time	space	
Breadth-first search	Y	Y, if ¹	O(bď)	O(b ^d)	
Uniform-cost search ²	Y	Y	O(b ^{C*/ε})	O(b ^{C*/ε})	
Depth-first search	Ν	Ν	O(b ^m)	O(bm)	
Iterative deepening	Y	Y, if ¹	O(bď)	O(bd)	

- 1. edge cost constant, or positive non-decreasing in depth
- edge costs $\geq \varepsilon > 0$. C* is the best goal path cost.

Performance of search algorithms on trees

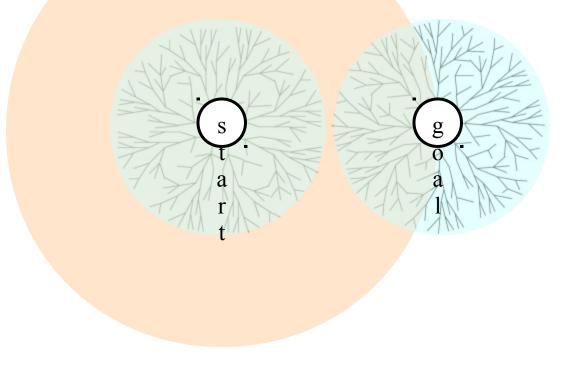

b: branching factor (assume finite) d: goal depth m: graph depth

- 1. edge cost constant, or positive non-decreasing in depth
- edge costs $\geq \varepsilon > 0$. C* is the best goal path cost.

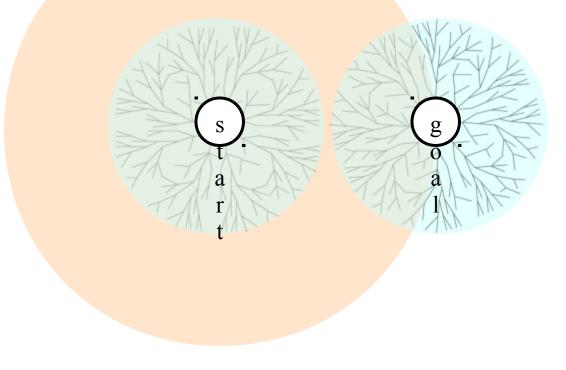

Bidirectional search

- Breadth-first search from both start and goal
- Fringes meet
- Generates O(b^{d/2}) instead of O(b^d) nodes

Bidirectional search

- But
 - The fringes are O(b^{d/2})
 - How do you start from the 8-queens goals?

Performance of search algorithms on trees

b: branching factor (assume finite) d: goal depth m: graph depth

	Complete	optimal	time	space	
Breadth-first search	Y	Y, if ¹	O(bď)	O(b ^d)	
Uniform-cost search ²	Y	Υ	O(b ^{C*/ε})	O(b ^{C*/ε})	
Depth-first search	Ν	Ν	O(b ^m)	O(bm)	
Iterative deepening	Y	Y, if ¹	O(bď)	O(bd)	
Bidirectional search ³	Y	Y, if ¹	O(b ^{d/2})	O(b ^{d/2})	

1. edge cost constant, or positive non-decreasing in depth

- edge costs $\geq \varepsilon > 0$. C* is the best goal path cost.
- both directions BFS; not always feasible.

If state space graph is not a tree

• The problem: repeated states

- Ignore the danger of repeated states: wasteful (BFS) or impossible (DFS). Can you see why?
- How to prevent it?

If state space graph is not a tree

- We have to remember already-expanded states (CLOSED).
- When we take out a state from the fringe (OPEN), check whether it is in CLOSED (already expanded).
 - If yes, throw it away.
 - If no, expand it (add successors to OPEN), and move it to CLOSED.

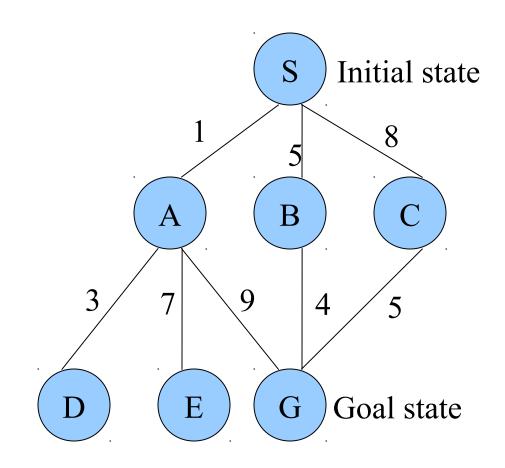

If state space graph is not a tree

- BFS:
 - Still O(b^d) space complexity, not worse
- DFS:
 - Known as Memorizing DFS (MEMDFS)
 - Space and time now O(min(N, b^M)) much worse!
 - N: number of states in problem
 - M: length of longest cycle-free path from start to anywhere
 - Alternative: Path Check DFS (PCDFS): remember only expanded states on current path (from start to the current node)
 - Space O(*M*)
 - Time O(*b^M*)

Path Checking DFS

- 1.Maintain a "prefix" path from root to current node, initially empty.
- 2.Pop a state s. If s in prefix, skip to next pop
- 3.Goal-checking s.
- 4.s comes with a backpointer to its parent p. The prefix should contain p somewhere as in initial, ..., p, ...
- 5.Remove everything after p and put s there, so prefix is now initial, ..., p, s.
- 6.When you generate a successor t of s, check if t is in prefix or stack. If no, push t to the stack; if yes, do not push it.

Example

(All edges are directed, pointing downwards)

Nodes expanded by:

- Depth-First Search: S A D E G
 Solution found: S A G
- Breadth-First Search: SABCDEG
 Solution found: SAG
- Uniform-Cost Search: S A D B C E G
 Solution found: S B G (This is the only uninformed search that worries about costs.)
- Iterative-Deepening Search: SABCSADEG
 Solution found: SAG

Depth-First Search

expanded						
node	n	ode	es	1:	ist	Ē.
						÷
	{	S	}			
S	{	А	В	С	}	
A	{	D	Е	G	В	$C \}$
D	{	Е	G	В	С	}
E	{	G	В	С	}	
G	{	В	С	}		

Solution path found is S A G <-- this G has cost 10 Number of nodes expanded (including goal node) = 5

Breadth-First Search

expanded	
node	nodes list
	{ S }
S	{
А	{ B C D E G }
В	{ C D E G G' }
С	{ D E G G
D	{ E G G' G" }
E	{ G G' G" }
G	{ G' G" }

Solution path found is S A G <-- this G also has cost 10 Number of nodes expanded (including goal node) = 7

Uniform-Cost Search

```
expanded
node
           nodes list
0.0010.0010.0010
            _____
            { S }
        { A(1) B(5) C(8) }
  S
           \{ D(4) B(5) C(8) E(8) G(10) \} (note, we don't return G)
  A
           { B(5) C(8) E(8) G(10) }
 D
           { C(8) E(8) G(9) G(10) }
  В
 С
           { E(8) G(9) G(10) G(13) }
            { G(9) G(10) G(13) }
  E
 G
            { }
```

Solution path found is S B G <-- this G has cost 9, not 10 Number of nodes expanded (including goal node) = 7

What you should know

- Problem solving as search: state, successors, goal test
- Uninformed search
 - Breadth-first search
 - Uniform-cost search
 - Depth-first search
 - Iterative deepening
 - Bidirectional search

- Can you unify them (except bidirectional) using the same algorithm, with different priority functions?
- Performance measures
 - Completeness, optimality, time complexity, space complexity
