Generalizing Word Embeddings using Bag of Subwords

Jinman Zhao, Sidharth Mudgal, Yingyu Liang

Word Embeddings

Belgium officially the Kingdom of Belgium, is a country in Western Europe bordered by France, the Netherlands, Germany and Luxembourg. It covers an area of 30,528 square kilometres (11,787 sq mi) and has a population of more than 11.4 million. The capital and largest city is Brussels; other major cities are Antwerp, Ghent, Charleroi and Liège. The sovereign state of Belgium is a federal constitutional monarchy with a parliamentary system of governance. Its institutional organisation is complex and is structured on both regional and linguistic grounds.
Word Embedding and Vocabulary

Word embedding:  \text{word} \mapsto \text{word vector}

Learnt from large text corpus.

Essential to many neural-network based approaches for NLP tasks.

Many popular word embedding techniques assume fixed-size vocabularies.

E.g. word2vec (Mikolov et al., 2013), GloVe (Pennington et al., 2014).

They have little to do with out-of-vocabulary (OOV) words!
1. Estimating word vectors for rare or unseen words can be crucial. Understanding new trending terms.

2. We can often guess the meaning of the word from its spelling.

   “preEMNLP” probably means “before EMNLP”.
   +ese means the people of some place.
   Chemical names.
Generalize to OOV words?

1. Estimating word vectors for rare or unseen words can be crucial.
   Understanding new trending terms.

2. We can often guess the meaning of the word from its spelling.
   “preEMNLP” probably means “before EMNLP”.
   +ese means the people of some place.
   Chemical names.

0. Existence of good pre-trained vectors (with fixed-size vocabularies).
Our Approach: A Learning Task

Generalizes pre-trained word embeddings

\[
\text{Vocabulary} \rightarrow \mathbb{R}^n
\]

\[
\text{word} \rightarrow \text{word vector}
\]

towards OOV words by using them as training data and learning a mapping

\[
\text{spelling} \rightarrow \text{word vector}
\]

No context is needed!
Our Bag-of-Subwords Model

Parameters: a lookup table maps character n-grams to vectors.

Word vector = average of the vectors of all its character n-grams.

Limit the sizes of character n-grams to be within $l_{\text{min}}$ and $l_{\text{max}}$.

Training: minimize mean square loss between BoS vector and target vector for all words in the vocabulary.
Bag-of-Subwords Model

In-vocabulary word

Arbitrary “word”

“precedent”

Minimize MSE for in-vocab words

MIMICK (Pinter et al. 2017) tackles the same task using a character-level bidirectional LSTM model.

fastText (Bojanowski et al., 2017) uses the same subword-level character n-gram model but is trained over large text corpora.
## Word Similarity Task

<table>
<thead>
<tr>
<th>Word pairs</th>
<th>Human label</th>
<th>Induced similarity</th>
</tr>
</thead>
<tbody>
<tr>
<td>love, sex</td>
<td>6.77</td>
<td>0.6</td>
</tr>
<tr>
<td>tiger, cat</td>
<td>7.35</td>
<td>correlation 0.5</td>
</tr>
<tr>
<td>book, paper</td>
<td>7.46</td>
<td>0.6</td>
</tr>
<tr>
<td>computer, keyboard</td>
<td>7.62</td>
<td>0.8</td>
</tr>
</tbody>
</table>

\[
\cos(v_{w1}, v_{w2})
\]
Our method almost triples the correlation score on common and rare words compared to MIMICK.
Our method matches the performance with fastText on rare words without access to contexts.

Spelling is effective!
Word Similarity Task

Target vectors:
- English PolyGlot vectors
- Google word2vec vectors

Evaluation sets:
- RW = Stanford RareWord
- WS = WordSim353

Other approach:
- Edit distance
- fastText over Wikipedia dump

Table 1: Target vectors statistics and word similarity task scores in Spearman’s $\rho \times 100$. In parentheses are OOV rates.

<table>
<thead>
<tr>
<th></th>
<th>Dim.</th>
<th># Tokens</th>
<th>RW</th>
<th>WS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Polyglot</td>
<td>64</td>
<td>100k</td>
<td>41(58%)</td>
<td>45(5%)</td>
</tr>
<tr>
<td>Google</td>
<td>300</td>
<td>160k</td>
<td>53(11%)</td>
<td>69(1%)</td>
</tr>
</tbody>
</table>

<td>VerbForm=Inf</td>
<td>Number=Sing</td>
</tr>
</tbody>
</table>
Joint Prediction of Part-of-Speech Tags and Morphosyntactic Attributes

MIMICK (Pinter et al. 2017).
Our method **consistently outperforms** MIMICK in all the 23 languages tested within the universal dependency (UD) dataset.
<table>

</tbody>
</table>

Table 3: POS tagging accuracy and morphosyntactic attributes micro F1 over 23 languages (UD 1.4). In parentheses are the gains to MIMICK.
Efficiency

Training time.
Our model takes only 3.5 s/epoch to train over English PolyGlot vectors with a naive single-thread CPU-only Python implementation and a usual desktop PC.
Conclusion

A surprisingly simple and fast method to extend pre-trained word vectors towards out-of-vocabulary words, **without using any context**.

The intrinsic and extrinsic evaluations show that our model’s ability in capturing lexical knowledge and generating good vectors, **using only spellings**.

Can we do more or better with spellings only or with minimal extra context?
Thanks for listening!

Q & A
