Exploiting Dead Value Information

To appear in MICRO-30

Milo M. Martin, Amir Roth, and Charles N. Fischer

1997 University of Wisconsin-Madison Architecture Affiliates Meeting
October 15, 1997

This document contains the text and graphs from a poster presentation. The pseudo code examples have not been included but are included in the MICRO-30 paper.

Paper available at: `http://www.cs.wisc.edu/~milo/micro30.ps`

Motivation

- **The hardware does not know when a register value is dead**
- **A dead value is no longer needed for continued correct execution**
- **However, the compiler has information about future register usage**

*** An opportunity for compiler/hardware interaction ***

- **Communicating this Dead Value Information (DVI) to the hardware enables optimizations**

Providing DVI

- **The information can be provided in two ways:**
  - **Explicitly by new instructions**
  - **Implicitly by procedure calling conventions**
- **A bit table is used to track the dead/live status of each register**
- **New *live-load* and *live-store* instructions added for saves and restores**

Register File Size Reduction

- **Registers holding dead values can be freed and used for register renaming**
- **This reduces the size requirements of the physical register file**
- **Allows for a higher IPC for a given register size:**
- **If the register file is constraining the clock cycle time, reducing the register file size can lead to overall performance gains**
- **Here we use a register file timing model to calculate overall performance (IPC x clock rate)**

Procedure Call Save/Restore Elimination

- **Dead registers do not need to be saved on procedure calls or restored on procedure returns**
- **Problem: The compiler does not know what registers are live into a procedure**
- **Solution: Use dead value information to track liveness dynamically**

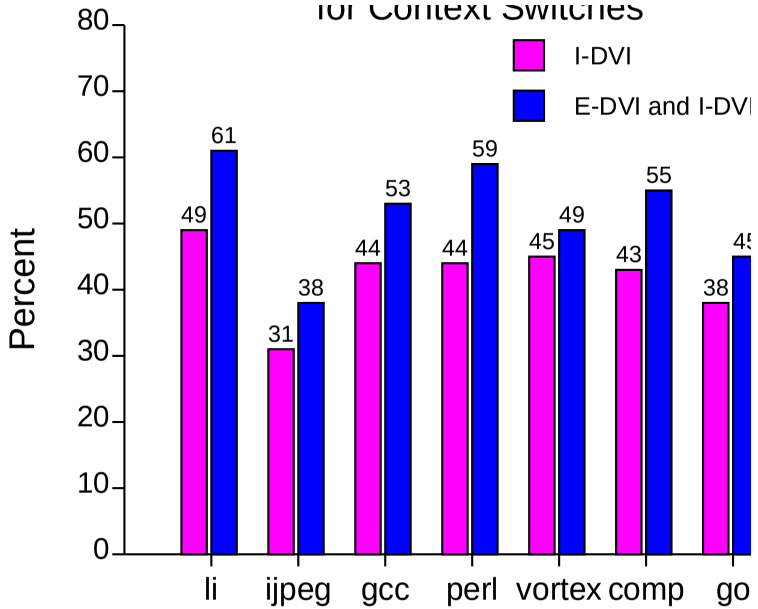
Context Switch Save/Restore Elimination

- **Dead values do not need to be saved or restored on context switches or thread switches**
- **Register save and restore time can be significant for thread switches**



Results

- **Reduces physical register size by 22%**
- **Removes 51% of context switch save and restores**
- **Eliminates 46% of callee saves which results in IPC improvements of nearly 5%**

Conclusions

- **Our use of DVI requires:**
  - **+ Only a few new instructions**
  - **+ Well known compiler techniques**
  - **+ Limited additional hardware structures**
- **Our optimizations becomes more important as C++ and Java become widespread**
- **Open question: What implications do these results have for future ISAs and calling conventions**
