

# CS354: Machine Organization and Programming

Lecture 9  
Wednesday the September 23<sup>th</sup> 2015

Section 2  
Instructor: Leo Arulraj

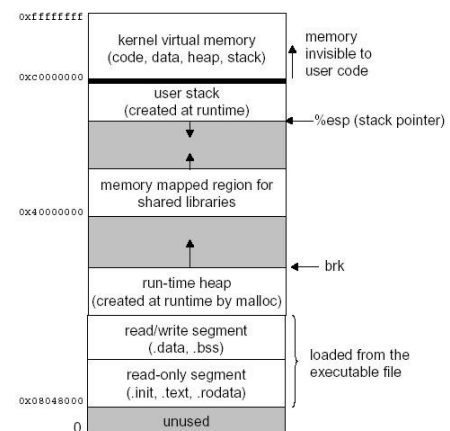

© 2015 Karen Smoler Miller  
© Some diagrams and text in this lecture from CSAPP lectures by Bryant & O'Hallaron

## Class Announcements

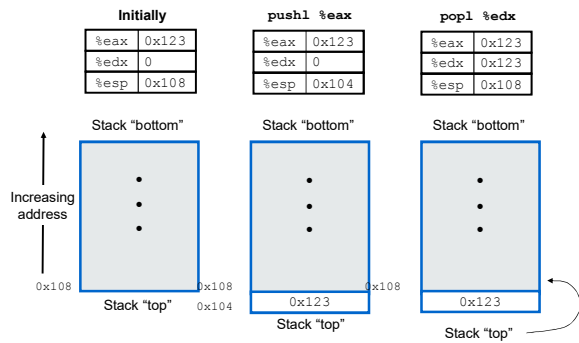

1. Take **backups of your C files** periodically.  
Saves lot of work in case bad things happen.
2. Brief session on C Programming aspects relevant to Assignment 1 in later part of next lecture. (Turns out I cannot go into details because that is part of the assignment).

## Lecture Overview

- Stack related Data Movement operations
- Data Movement example
- Arithmetic instructions

### Stack Example: pushl, popl

### pushl and popl

- `pushl %ebp` is equivalent to:  
`subl $4, %esp`  
`movl %ebp, (%esp)`
- `popl %eax` is equivalent to:  
`movl (%esp), %eax`  
`addl $4, %esp`

### Data Movement Example (Trace through during lecture)

<pre>.data value:     .long 52713 heapvar:     .long 0x5000 .text .globl main main:     movl \$103, %eax     movl %eax, %esi     movl value, %ebx</pre>	<p>Continued from left column:</p> <pre>    movl %esp, %ecx     movl %eax, (%ecx)     movl heapvar, %eax     movl 8(%eax), %edx     pushl %edx     pushl \$207     popl %edi     movl \$3, %ecx     movl (%eax, %ecx, 4), %edx     ret</pre>
---------------------------------------------------------------------------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

### Arithmetic Instructions

<code>leal</code>	<code>S, D</code>	(load effective address) D gets the address defined by S
<code>inc</code>	D	D gets D + 1 (two's complement)
<code>dec</code>	D	D gets D - 1 (two's complement)
<code>neg</code>	D	D gets -D (two's complement additive inverse)
<code>add</code>	S, D	D gets D + S (two's complement)
<code>sub</code>	S, D	D gets D - S (two's complement)
<code>imul</code>	S, D	D gets D * S (two's complement integer multiplication)

### More Arithmetic Instructions, with 64 bits of results

<code>imull</code>	<b>S</b>	<code>%edx  %eax</code> gets 64-bit <i>two's complement</i> product of <b>S</b> * <code>%eax</code>
<code>mull</code>	<b>S</b>	<code>%edx  %eax</code> gets 64-bit <i>unsigned</i> product of <b>S</b> * <code>%eax</code>
<code>idivl</code>	<b>S</b>	<i>two's complement</i> division of <code>%edx  %eax</code> / <b>S</b> ; <code>%edx</code> gets remainder, and <code>%eax</code> gets quotient
<code>divl</code>	<b>S</b>	<i>unsigned</i> division of <code>%edx  %eax</code> / <b>S</b> ; <code>%edx</code> gets remainder, and <code>%eax</code> gets quotient

Notice *implied* use of `%eax` and `%edx`.

`leal` is commonly used to calculate addresses. Examples:

```
leal 8(%eax), %edx
```

- 8 + contents of `eax` goes into `edx`
- used for pointer arithmetic in C
- very convenient for acquiring the address of an array element

```
leal (%eax, %ecx, 4), %edx
```

- contents of `eax` + 4 \* contents of `ecx` goes into `edx`
- *even more convenient* for addresses of array elements, where `eax` has base address, `ecx` has the index, and each element is 4 bytes

### Examples

Assume `%eax` is `x` and `%ecx` is `y`  
and `%edx=10`, address 10 has value 100

1. `leal 6(%eax), %edx` :: ?
2. `leal 9(%eax,%ecx,2), %edx` :: ?
3. `addl %ecx, (%edx)` :: ?
4. `decl %ecx` :: ?

### Examples

Assume `%eax` is `x` and `%ecx` is `y`  
and `%edx=10`, address 10 has value 100

1. `leal 6(%eax), %edx` :: 6+x
2. `leal 9(%eax,%ecx,2), %edx` :: 9 + x + 2y
3. `addl %ecx, (%edx)` :: (y + 100) stored @ address 10
4. `decl %ecx` :: (y-1) stored in `%ecx`

## Examples

Assume x at %ebp+8, y at %ebp+12, z at %ebp+16

1 movl 16(%ebp), %eax	$z$
2 leal (%eax,%eax,2), %eax	$z*3$
3 sall \$4, %eax	$t2 = z*48$
4 movl 12(%ebp), %edx	$y$
5 addl 8(%ebp), %edx	$t1 = x+y$
6 andl \$65535, %edx	$t3 = t1 \& 0xFFFF$
7 imull %edx, %eax	$t4 = t2*t3$
