

Welcome back!

MEMORY VIRTUALIZATION

Shivaram Venkataraman

CS 537, Fall 2024

ADMINISTRIVIA

- Project 2 is due Sept 24th **Tuesday**
- Project 1 grading in progress (soon?)
- Midterm I: Oct 15th at 5.45pm
- Conflict form → *Piazza*

AGENDA / LEARNING OUTCOMES

Memory virtualization

What are main techniques to virtualize memory?

What are their benefits and shortcomings?

RECAP

MEMORY VIRTUALIZATION

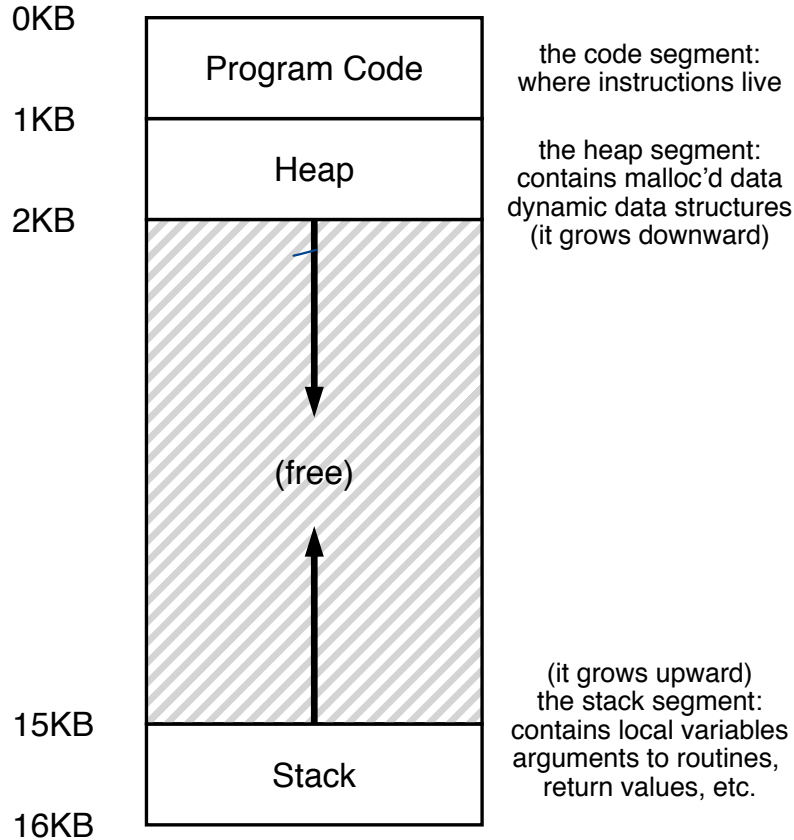

Transparency: Process is unaware of sharing

Protection: Cannot corrupt OS or other process memory

Efficiency: Do not waste memory or slow down processes

Sharing: Enable sharing between cooperating processes

RECAP: WHAT IS IN ADDRESS SPACE?

Static: Code and some global variables

Dynamic: Stack and Heap

HOW TO VIRTUALIZE MEMORY

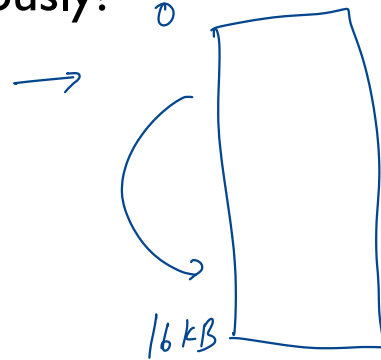

Problem: How to run multiple processes simultaneously?

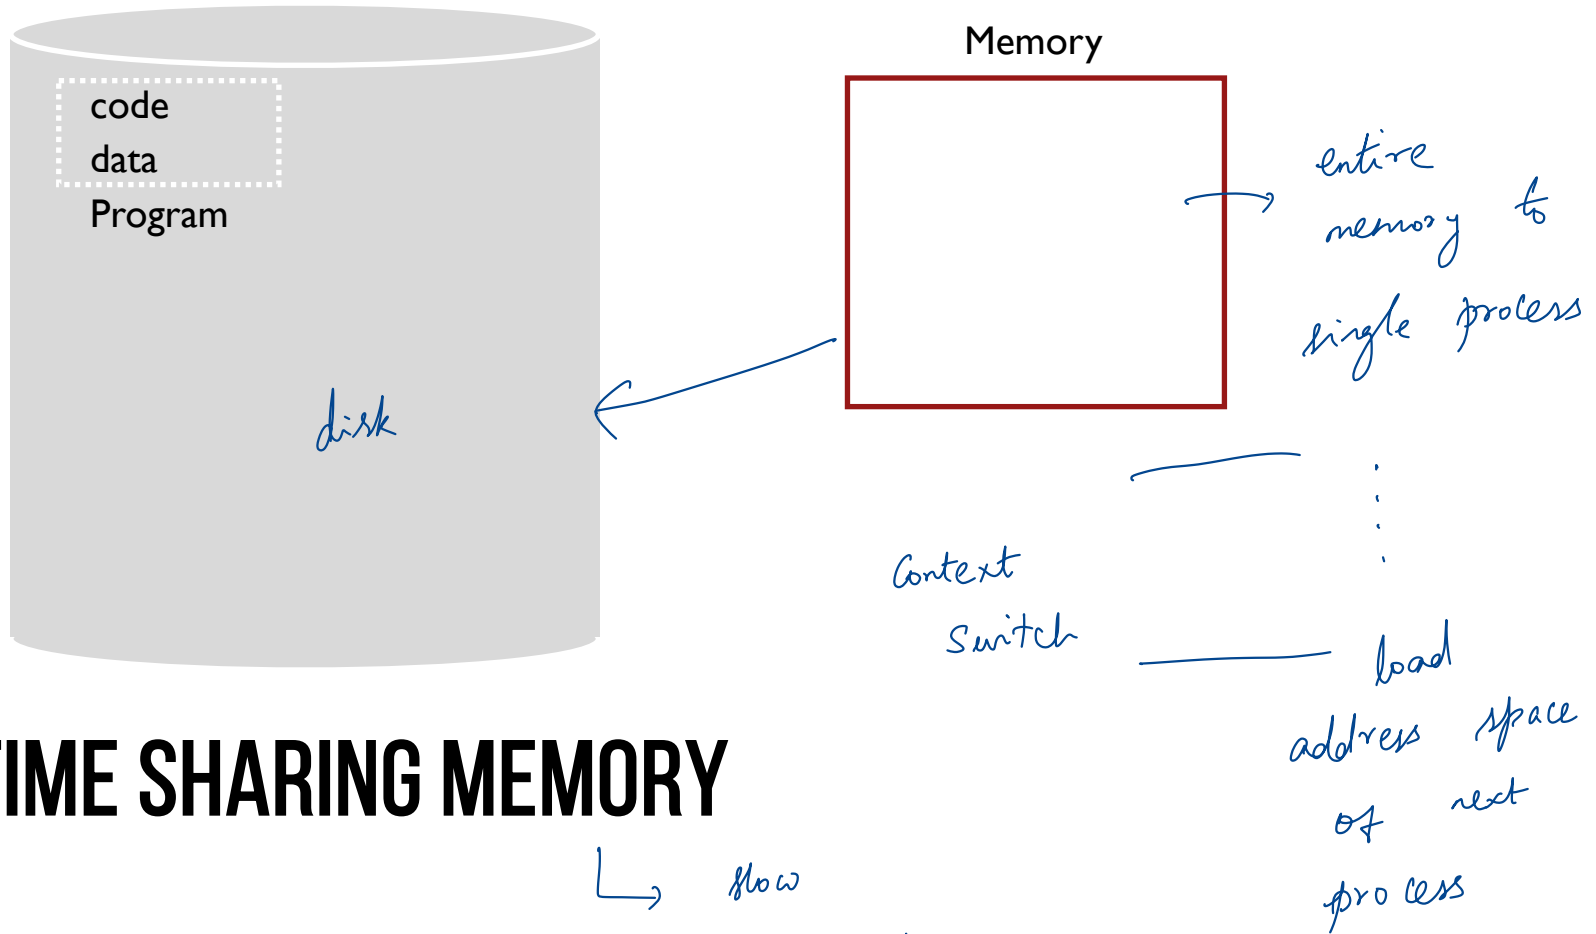

Addresses are “hardcoded” into process binaries

How to avoid collisions?

Possible Solutions for Mechanisms:

1. Time Sharing
2. Static Relocation
3. Base
4. Base+Bounds

1) TIME SHARING MEMORY

↳ slow
inefficient

2) STATIC: LAYOUT IN MEMORY

virtual addresses = 0

Physical address = 4 KB

process 1

```
0x1010: movl 0x8(%rbp), %edi
0x1013: addl $0x3, %edi
0x1019: movl %edi, 0x8(%rbp)
```

→ adding 1000

→ adding 3000

```
0x3010: movl 0x8(%rbp), %edi
0x3013: addl $0x3, %edi
0x3019: movl %edi, 0x8(%rbp)
```

→ Protection

3) DYNAMIC RELOCATION

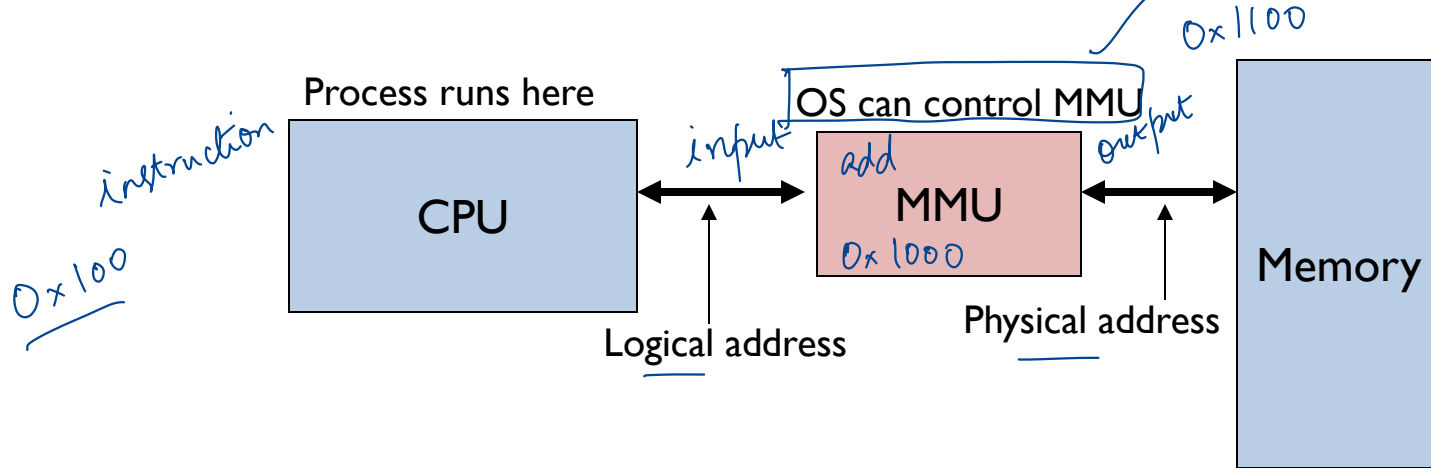

Goal: Protect processes from one another

Requires hardware support

- Memory Management Unit (MMU)

MMU dynamically changes process address at every memory reference

- Process generates **logical** or **virtual** addresses (in their address space)
- Memory hardware uses **physical** or **real** addresses

HARDWARE SUPPORT FOR DYNAMIC RELOCATION

Privileged (protected, kernel) mode: OS runs

- When enter OS (trap, system calls, interrupts, exceptions)
- Allows certain instructions to be executed
(Can manipulate contents of MMU)
- Allows OS to access all of physical memory

*instructions only
valid in kernel mode*

User mode: User processes run

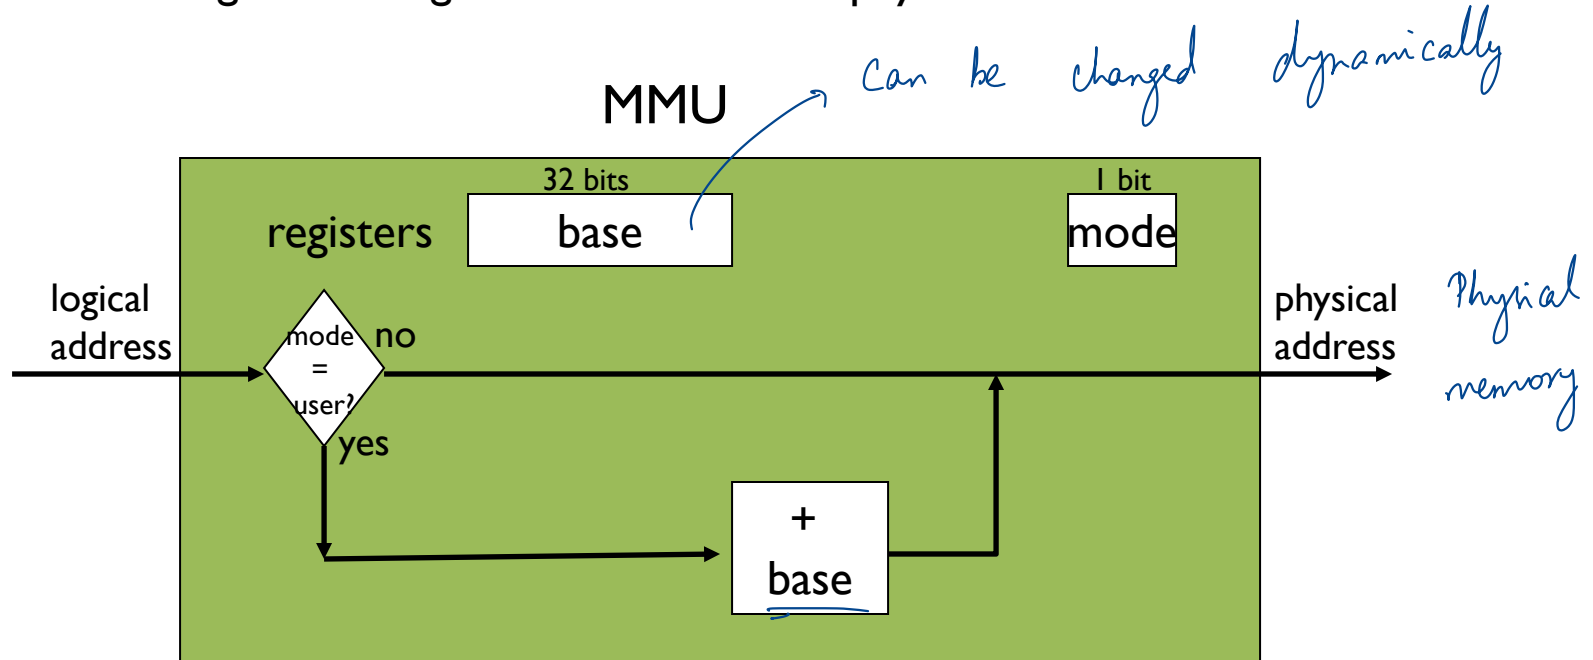

- Perform translation of logical address to physical address

↳ using the MMU

IMPLEMENTATION OF DYNAMIC RELOCATION: BASE REG

Translation on every memory access of user process

MMU adds base register to logical address to form physical address

DYNAMIC RELOCATION WITH BASE REGISTER

Translate virtual addresses to physical by adding a fixed offset each time.

Store offset in base register

Each process has different value in base register

Dynamic relocation by changing value of base register!

Base Register for P1 = 2048

Base Register for P2 = 3072

Virtual
 P1: load 10, R1
 P1: load 200, R1
 P2: load 500, R1

Physical *load*
 $2048 + 10 = 2058$
 $2048 + 200$
 $3072 + 500 = 3572$

VISUAL EXAMPLE OF DYNAMIC RELOCATION: BASE REGISTER

base P1
= 1024

base P2
= 4096

Virtual

→ P1: load 100, R1
P2: load 100, R1
P2: load 1000, R1
P1: load 1000, R1
P1: store 3072, R1

Can P1 hurt P2?

Physical

load 1124, R1
load 4196, R1
load 5196, R1
load 2024, R1

1024 + 3072

= 4096

4) DYNAMIC WITH BASE+BOUNDS

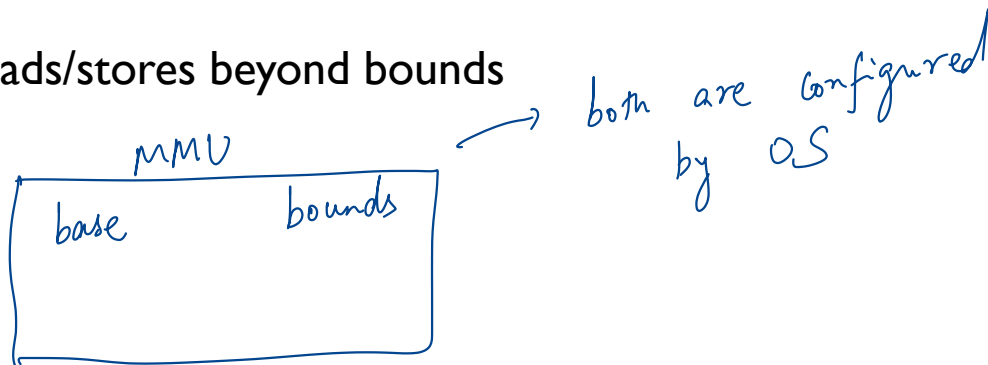

Idea: limit the address space with a bounds register

Base register: smallest physical addr (or starting location)

Bounds register: size of this process's virtual address space

- Sometimes defined as largest physical address (base + size)

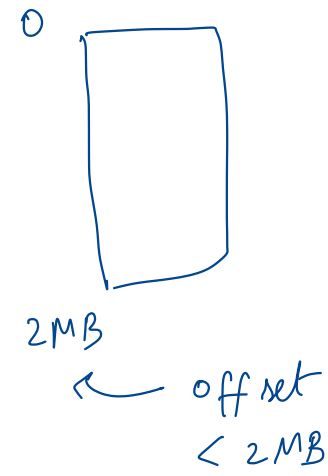

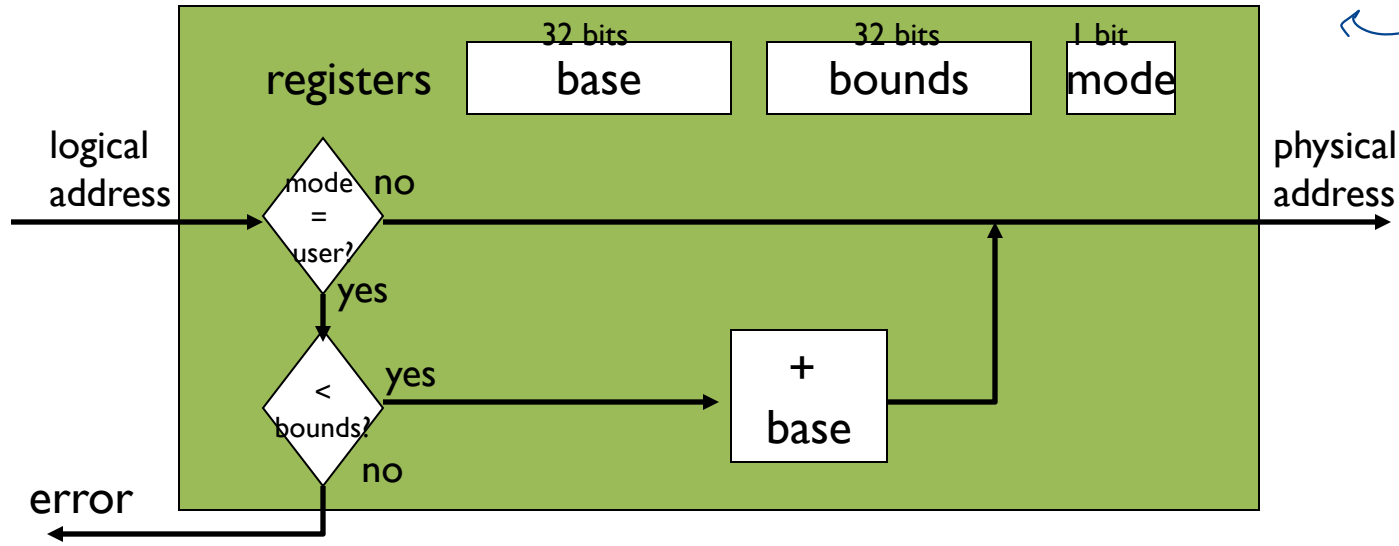

→ OS kills process if process loads/stores beyond bounds

IMPLEMENTATION OF BASE+BOUNDS

Translation on every memory access of user process

- MMU compares logical address to bounds register
if logical address is greater, then generate error
- MMU adds base register to logical address to form physical address

MANAGING PROCESSES WITH BASE AND BOUNDS

Context-switch: Add base and bounds registers to proc struct

OS Steps

- Change to privileged mode
- Save base and bounds registers of old process
- Load base and bounds registers of new process
- Change to user mode and jump to new process

from MMU
to MMU

Protection requirement

- User process cannot change base and bounds registers
- User process cannot change to privileged mode

every process
addr space
needs to be
contiguous

BASE AND BOUNDS

Advantages

Provides protection (both read and write) across address spaces

Supports dynamic relocation

Can place process at different locations initially and move address spaces

Simple, inexpensive implementation: Few registers, little logic in MMU

Disadvantages

Each process must be allocated contiguously in physical memory

Must allocate memory that may not be used by process

No partial sharing: Cannot share parts of address space

Efficiency

Sharing

QUIZ 4

<https://tinyurl.com/cs537-fa24-q4>

```
unsigned long A = 3; →  
int main(int argc, char *argv[]) {  
    int B = 7;  
    short *P = malloc(5 * sizeof(short));  
}
```

static data / code

B stack

P stack

P[2]
heap

QUIZ 4

<https://tinyurl.com/cs537-fa24-q4>

Address space size 1K \longrightarrow max memory

Physical memory of size 16K

process

Base: 0x00003cb5 (decimal 15541)

Limit: 492

Virtual address

433 < 492

✓ add to base

$$15541 + 433 = 15974$$

VA = 913 X

5) SEGMENTATION

Virtual memory

Divide address space into logical segments

- Each segment corresponds to logical entity in address space (code, stack, heap)

Each segment has separate base + bounds register

segment →

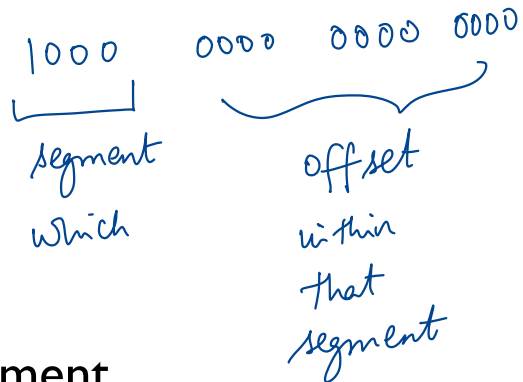

2^n-1

SEGMENTED ADDRESSING

Process now specifies segment and offset within segment

How does process designate a particular segment?

- Use part of logical address (*virtual address*)
 - Top bits of logical address select segment
 - Low bits of logical address select offset within segment

What if small address space, not enough bits?

- Implicitly by type of memory reference
- Special registers

SEGMENTATION IMPLEMENTATION

MMU contains Segment Table (per process)

- Each segment has own base and bounds, protection bits
- Example: 14 bit logical address, 4 segments; \rightarrow number

$\log_2(4) = 2$ bits to select segment

Permission

How many bits for segment?

2

How many bits for offset?

$14 - 2 = 12$
bits

Segment	<u>Base</u>	Bounds	<u>R</u> <u>W</u>
0 .	0x2000	0x6ff	1 0
1 .	0x0000	0x4ff	1 1
2 .	0x3000	0xfff	1 1
3 .	0x0000	0x000	0 0

remember:
1 hex digit \rightarrow 4 bits

VISUAL INTERPRETATION

14 bit
addr
space

Virtual (hex)

load 0x2010, R1
 ↙ ↘
 2 bits 12 bits

load 0x1010, R1

load 0x1100, R1

Physical

stack segment

$0x1600 + \underline{0010}$
 $= 0x1610$

$0x400 + \underline{0010}$
 $= 0410$

$0x400 + 0100$
 $= 0x500$

- Segment numbers:
- 0: code+data
 - 1: heap \xrightarrow{s}
 - 2: stack

Segment numbers:

0: code+data

1: heap

2: stack

Virtual

load 0x2010, R1

load 0x1010, R1

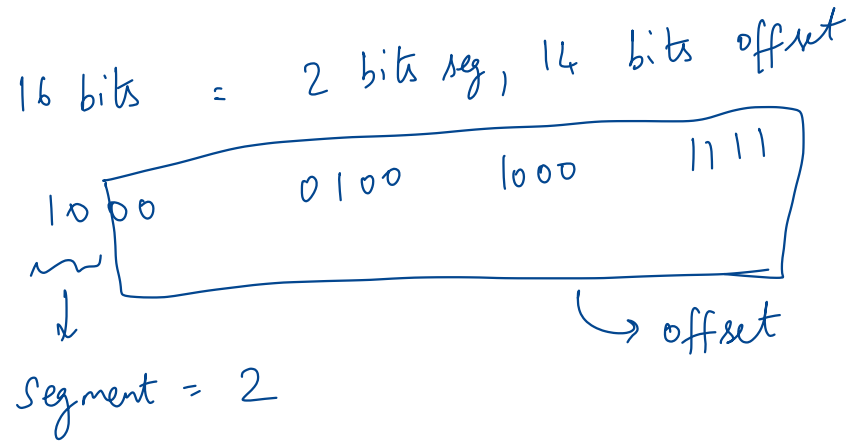

load 0x1100, R1

Physical

$0x1600 + 0x010 = 0x1610$

$0x400 + 0x010 = 0x410$

$0x400 + 0x100 = 0x500$

HOW DOES THIS LOOK IN X86

Stack Segment (SS): Pointer to the stack

Code Segment (CS): Pointer to the code

Data Segment (DS): Pointer to the data

Extra Segment (ES): Pointer to extra data

F Segment (FS): Pointer to more extra data

G Segment (GS): Pointer to still more extra data

NOTE: HOW DO STACKS GROW ?

Stack goes $16K \rightarrow 12K$, in physical memory is $28K \rightarrow 24K$
 Segment base is at $28K$

Virtual address $0x3C00 = 15K$

\rightarrow top 2 bits (0x3) segment ref, offset is $0xC00 = 3K$

How do we make CPU translate that ?

Negative offset = subtract max segment from offset
 $= 3K - 4K = -1K$

Add to base = $28K - 1K = 27K$

bound or segment size

ADVANTAGES OF SEGMENTATION

Protection

Enables sparse allocation of address space

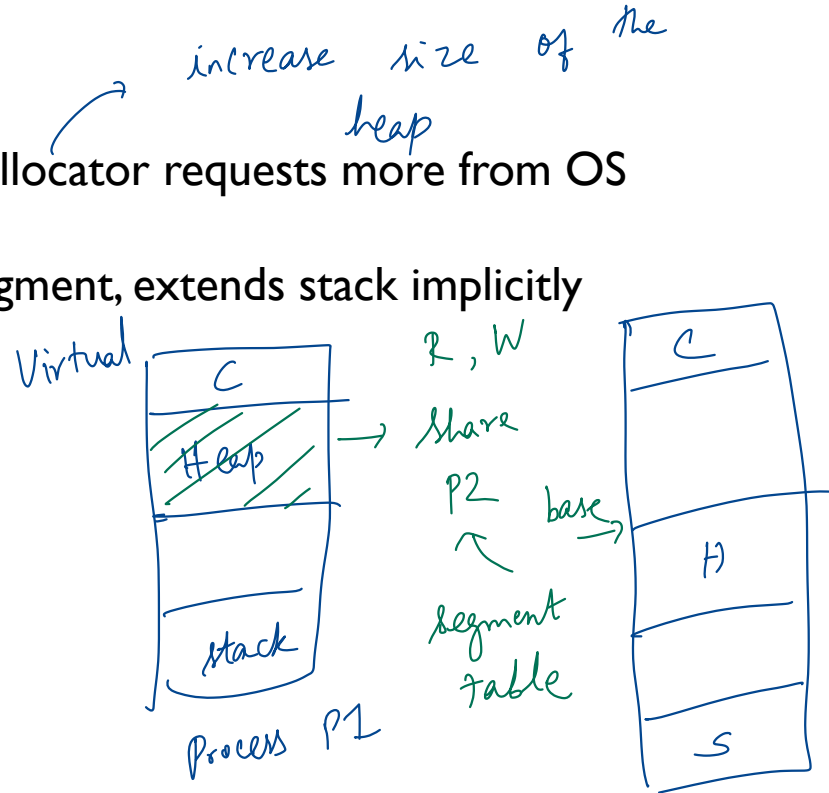

Stack and heap can grow independently

- Heap: If no data on free list, dynamic memory allocator requests more from OS (e.g., UNIX: malloc calls sbrk())
- Stack: OS recognizes reference outside legal segment, extends stack implicitly

Different protection for different segments

- Enables sharing of selected segments
- Read-only status for code

Supports dynamic relocation of each segment

DISADVANTAGES OF SEGMENTATION

Each segment must be allocated contiguously

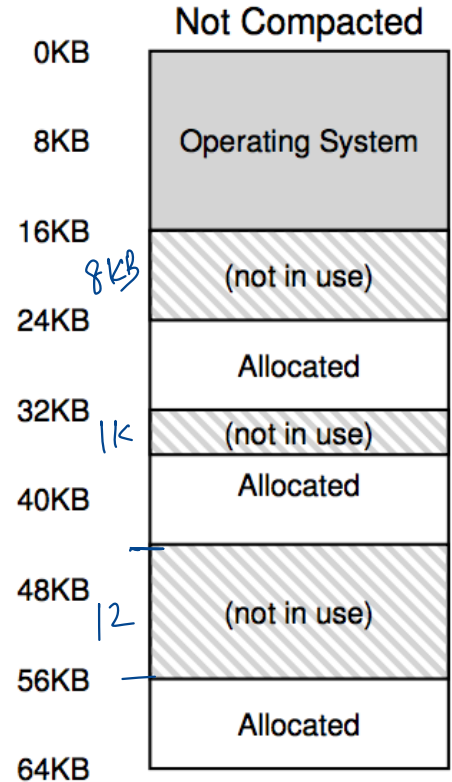

May not have sufficient physical memory for large segments?

External Fragmentation

Paging

24 KB in one segment

↳ copying / moving overhead

NEXT STEPS

Project 2: Due soon!

Next class: Paging, TLBs and more!
