The \texttt{alg} package*

Staffan Ulfberg
staffanu@nada.kth.se

13 March 2001

Abstract

This package defines two environments for typesetting algorithms in \TeX. Lines are automatically numbered and can be referenced, the means for easy indentation is provided, and algorithms can be made floating bodies if desired.

1 Introduction

\texttt{algtab} \texttt{alg.sty} defines two environments. The \texttt{algtab} environment is used to typeset an algorithm with automatically numbered lines; it also takes care of indentation. The \texttt{algorithm} environment can be used to encapsulate the \texttt{algtab} environment in a floating body together with a header, a caption, etc. The package recognizes a few language options and changes its fixed output strings accordingly. Please tell the author of this package if you need support for another language!

1.1 The \texttt{algorithm} environment

The \texttt{algorithm} environment starts a floating body; its placement is decided by an optional argument that can be any combination of \texttt{t}, \texttt{b}, \texttt{p}, or \texttt{h}. By default, the placement \texttt{H} (Here!) is used, so the float does not float after all. See the description of the \texttt{float} package by Anselm Lingnau for more details about this. Inside the \texttt{algorithm} environment, the text will be indented from the left and right edges. It is possible to put a \texttt{caption} within the float, and also to generate a list of algorithms with the \texttt{listofalgorithms} command.

Notice that it is by no means necessary to use this environment to use the rest of the package.

1.2 Algorithm description

Three macros are defined to describe an algorithm’s name, parameters, and function. They may be used in the \texttt{algorithm} environment, or just anywhere before the \texttt{algtab} environment.

\*This file was last revised 13 March 2001.
\algdesscript \algdesscript takes one argument which is printed after the string “Description:” in boldface letters.
\alinout \alinout takes two arguments which are printed after the strings “Input:” and “Output:” respectively.

1.3 The \algtab environment
In the \algtab environment, an algorithm is typed line by line, separating lines by \. Every time a new line is started, it will be numbered in the left margin starting at line 1. A single “line” of the algorithm can span several lines of the page, but a line number will only be printed after each \ command. The current \ref value is also set, so that a label can be entered; it’s recommended that
\alglab \alglab is used for this purpose.
\algtab* \algtab* The \algtab environment has a star-form variant that suppresses line number generation; if the \alglab macro is used in this case, the supplied label argument is printed as-is in the left margin of the algorithm (where the line numbers usually are printed). The macro \algrf corresponds to \alglab in the way that it prints either the referenced label’s value, or the label name literally if no line numbers are used. However, \algrf can’t be used outside the \algtab environment: use \ref instead.
\alignme \alignme The \alignme macro can be used at the start of a line to suppress the printing of a line number on that line.
The \algtab environment indents the algorithm to make room for the line numbers; the \algtab* does not indent the algorithm by default. However, both environments take an optional argument specifying the amount of indentation that is desired.
\algbeg \algbeg There are two important macros, \algbeg and \algend, defined in the \algtab environment. These macros start and stop additional indentation respectively; they should always be used at the beginning of a line. These macros are already included in some of the macros that are special to the \algtab environment.

2 Example
This section shows how to typeset Algorithm 1 using the \alg package in \LaTeX: 
\begin{algorithm}[h]
\caption{Example of the \texttt{algorithm} environment. \label{alg:ex}}
\alinout{An ordered set $U=\{u_1,u_2,\ldots,u_n\}$.}
\alinout{The set’s maximum element, and a set $A$, $|A|=\log n$, containing the next largest element. (If $n=1$, then $A=\emptyset$).}
\algname{Max2}{$U$}
\begin{algtab}
\algif{$|U|=1$}
\algreturn $(u_1, \emptyset)$ \\
\algelsif{$|U|=2$}
\algifthenelse{$u_1>u_2$}{\algreturn $(u_1, \{u_2\})$}{\algreturn $(u_2, \{u_1\})$}
\algelse
$(b,B) \leftarrow$
\end{algtab}
\end{algorithm}
Algorithm 1: Example of the algorithm environment.

Input: An ordered set \( U = \{u_1, u_2, \ldots, u_n\} \).

Output: The set’s maximum element, and a set \( A, |A| = \log n \), containing the next largest element. (If \( n = 1 \), then \( A = \emptyset \).

\[
\text{MAX2}(U)
\]

1. if \( |U| = 1 \)
2. return \((u_1, \emptyset)\)
3. else if \( |U| = 2 \)
4. if \( u_1 > u_2 \) then return \((u_1, \{u_2\})\)
5. else return \((u_2, \{u_1\})\)
6. else
7. \((b, B) \leftarrow \text{MAX2}([u_i]_{i=1}^{\lfloor n/2 \rfloor})\)
8. \((c, C) \leftarrow \text{MAX2}([u_i]_{i=\lfloor n/2 \rfloor+1}^{n})\)
9. if \( b > c \) then return \((b, \{c\} \cup B)\)
10. else return \((c, \{b\} \cup C)\)

\[
\text{\algcall{Max2}}\{\{u_i\}_{i=1}^{\lfloor n/2 \rfloor}\}\text{\algcall{Max2}}\{\{u_i\}_{i=\lfloor n/2 \rfloor+1}^{n}\}
\]

\[
\text{\algifthenelse{b>c}{\algreturn{(b, \{c\} \cup B)}}{\algreturn{(c, \{b\} \cup C)}}}
\]

There is a list of all programming constructs available in the \texttt{algtab} environment at the end of this document. They work very much like the macros used above. As a general rule, if a macro doesn’t take an argument, a space character is included at the end of the macro definition. For example, type \texttt{$a=0$ \algor \algnot $b=0$} to produce “\(a = 0\) or not \(b = 0\).”

3 The Implementation

1 (*package)

The \texttt{float} package by Anselm Lingnau is used for floating algorithms.

2 \texttt{\RequirePackage{float, ifthen}}

Here are the variable declarations. \texttt{\algleftmarginwidth}, \texttt{\algrightmarginwidth}, \texttt{\alglinenowidth}, and \texttt{\algtabwidth} define the amount of indentation of the entire algorithm, the space reserved for line numbers, and the indentation made by \texttt{\algbegin} respectively.

3 \texttt{\newlength{\algleftmarginwidth}\setlength{\algleftmarginwidth}{.5in}}
4 \texttt{\newlength{\algrightmarginwidth}\setlength{\algrightmarginwidth}{.5in}}
5 \texttt{\newlength{\alglinenowidth}\setlength{\alglinenowidth}{1.2cm}}
6 \texttt{\newlength{\algtabwidth}\setlength{\algtabwidth}{.5cm}}
7 \texttt{\newlength{\alg@fromleft}}
8 \texttt{\newlength{\alg@tmplen}}
9 \texttt{\newsavebox{\alg@tmpbox}}
10 \texttt{\newcounter{alg@inmargin}\setcounter{alg@inmargin}{0}}
Strings used in captions and in the List of Algorithms differ in some languages. If a language is specified as an option to this package, that language is used. Otherwise, if the babel package is loaded, the selected babel language is used.

The following definitions set up the properties of the \texttt{algorithmfloat}.
\listofalgorithms The \listofalgorithms macro can be used to generate a list of all algorithms in a document.

\alg@margin The \alg@margin macro makes the text a bit narrower. It is used in the start of both the \algorithm and \algtab environments, and also in the \algname, \algdescript, and \alginout macros; it keeps track of if the text is already narrow, and in this case does nothing.

\alg@unmargin The \alg@unmargin macro resets any indentation made by \alg@margin.

\algorithm The \algorithm environment simply begins a float as defined above. Actually, the default is to use the placement parameter H, so that the algorithm will not really float. Inside the float all text is indented by \algleftmarginwidth and \algrightmarginwidth.

\algtab The \algtab environment is what does most of the formatting job; it’s called by \algtab and \algtab* defined below. The argument defines the amount of initial indentation. If the counter \alg@inmargin is zero, \algtab is not started within a float. In this case some room is made above and below it. Inside this environment, ^^M is let to the macro \alg@cr that is used to begin new lines. The \catcode for ^ is changed to admit blank input lines within an algorithm.
This environment sets \texttt{alg@linenums} true, which will make \texttt{algputlineno} write the current line number in the left margin.

\begin{algtab}[1][\texttt{alglinenowidth}] \end{algtab}

This environment works like \texttt{algtab} but sets \texttt{alg@linenums} false and uses zero indentation by default.

\begin{algtab*}[1][0cm] \end{algtab*}

The \texttt{alg@kill} macro removes the last box from the current horizontal list. It is used to remove the box containing the line number (label) when indentation is changed: in this case a new box for the label must be created.

\begin{algbegin}[1][\texttt{algtabwidth}] \end{algbegin}

This macro reverses the effect of a previous \texttt{algbegin}.

\begin{algend}[1][\texttt{algtabwidth}] \end{algend}

New lines are started using this macro. The line number is incremented and printed.

\begin{alg@cr} \end{alg@cr}

Line numbers are typeset as labels.
This is the macro that puts a label on the horizontal list. The label extends to the left of a zero-width box.

\newcommand{\alg@putlabel}[1]{{% 
  \alg@tmplen=\leftskip \advance\alg@tmplen-\alg@fromleft% 
  \makebox[0cm][r]{\makebox[\alg@tmplen][l]{#1}}}%

3.1 Macros for algorithm descriptions
