Error Detection in LALR Parsers

In bottom-up, LALR parsers syntax errors are discovered when a blank (error) entry is fetched from the parser action table.

Let's again trace how the following illegal CSX-lite program is parsed:

{ b + c = a; } Eof

} Eof Shift	{ b + c = a; } Eof

Parse Stack	Top State	Action	Remaining Inp
1 0	$\begin{array}{l} \mbox{Prog} \rightarrow \mbox{ { \bullet Stmts } } \mbox{ Eof} \\ \mbox{Stmts} \rightarrow \bullet \mbox{ Stmts } \\ \mbox{Stmts} \rightarrow \lambda \bullet \\ \mbox{Stmt} \rightarrow \bullet \mbox{ id } = \mbox{ Expr } ; \\ \mbox{Stmt} \rightarrow \bullet \mbox{ if } (\mbox{ Expr }) \end{array}$	Shift	b + c = a ; } Eof
4 1	Stmt \rightarrow id • = Expr ;	Error (blank)	+ c = a; } Eof

LALR is More Powerful

Essentially all LL(1) grammars are LALR(1) plus many more. Grammar constructs that confuse LL(1) are readily handled.

• Common prefixes are no problem. Since sets of configurations are tracked, more than one prefix can be followed. For example, in

Stmt \rightarrow id = Expr ; Stmt \rightarrow id (Args) ; after we match an id we have

 Left recursion is also not a problem. Since sets of configurations are tracked, we can follow a leftrecursive production *and* all others it might use. For example, in

 $\begin{array}{l} \textbf{Expr} \rightarrow \boldsymbol{\cdot} \ \textbf{Expr} \ \textbf{+} \ \textbf{id} \\ \textbf{Expr} \rightarrow \boldsymbol{\cdot} \ \textbf{id} \\ \text{we can first match an } \ \textbf{id} : \end{array}$

 $\textbf{Expr} \rightarrow \textbf{ id } \boldsymbol{\cdot}$

Then the **Expr** is recognized:

 $\textbf{Expr} \rightarrow \textbf{Expr} \boldsymbol{\cdot} \textbf{+} \textbf{id}$

The left-recursion is handled!

Grammar Engineering

Though LALR grammars are very general and inclusive, sometimes a reasonable set of productions is rejected due to shift/reduce or reduce/reduce conflicts.

In such cases, the grammar may need to be "engineered" to allow the parser to operate.

A good example of this is the definition of **MemberDecis** in CSX. A straightforward definition is

CS 536 Spring 2006

330

When we predict **MemberDecls** we

get:

 $\begin{array}{l} \mbox{MemberDecls} \rightarrow \bullet \mbox{FieldDecls} \mbox{MethodDecls} \\ \mbox{FieldDecls} \rightarrow \bullet \mbox{FieldDecl} \mbox{FieldDecls} \rightarrow \lambda \bullet \\ \mbox{FieldDecl} \rightarrow \bullet \mbox{int} \mbox{ id }; \end{array}$

Now int follows **FieldDecls** since **MethodDecls** \Rightarrow^+ int ...

Thus an unresolvable shift/reduce conflict exists.

The problem is that **int** is derivable from both **FieldDecIs** and **MethodDecIs**, so when we see an **int**, we can't tell which way to parse it (and FieldDecIs $\rightarrow \lambda$ requires we make an immediate decision!). If we rewrite the grammar so that we can delay deciding from where the int was generated, a valid LALR parser can be built:

When **MemberDecls** is predicted we have

 $\begin{array}{ll} \mbox{MemberDecls} \rightarrow \bullet \mbox{FieldDecl MemberDecls} \\ \mbox{MemberDecls} \rightarrow \bullet \mbox{MethodDecls} \\ \mbox{MethodDecls} \rightarrow \bullet \mbox{MethodDecl} \mbox{MethodDecls} \\ \mbox{MethodDecls} \rightarrow \lambda \bullet \\ \mbox{FieldDecl} \rightarrow \bullet \mbox{int id ;} \\ \mbox{MethodDecl} \rightarrow \bullet \mbox{int id () ; Body} \end{array}$

CS 536 Spring 2006

331

Now Follow(MethodDecls) = Follow(MemberDecls) = "}", so we have no shift/reduce conflict. After int id is matched, the next token (a ";" or a "(") will tell us whether a FieldDecl or a MethodDecl is being matched.

CS 536 Spring 2006

• LL and LALR parsers detect an syntax error as soon as the first invalid token is seen.

Neither parser can match an invalid program prefix. If a token is matched it *must be* part of a valid program prefix. In fact, the prediction made or the stacked configuration sets *show* a possible derivation of the token accepted so far.

• All LL and LALR grammars are unambiguous.

LL predictions are always unique and LALR shift/reduce or reduce/reduce conflicts are disallowed. Hence only one valid derivation of any token sequence is possible.

Properties of LL and LALR Parsers

• Each prediction or reduce action is guaranteed correct. Hence the entire parse (built from LL predictions or LALR reductions) must be correct.

This follows from the fact that LL parsers allow only one valid prediction per step. Similarly, an LALR parser never skips a reduction if it is consistent with the current token (and *all* possible reductions are tracked).

CS 536 Spring 2006

334

 All LL and LALR parsers require only linear time and space (in terms of the number of tokens parsed).

The parsers do only fixed work per node of the concrete parse tree, and the size of this tree is linear in terms of the number of leaves in it (even with λ -productions included!).

335

Symbol Tables in CSX

CSX is designed to make symbol tables easy to create and use.

There are three places where a new scope is opened:

- In the class that represents the program text. The scope is opened as soon as we begin processing the classNode (that roots the entire program). The scope stays open until the entire class (the whole program) is processed.
- When a methodDeclNode is processed. The name of the method is entered in the top-level (global) symbol table. Declarations of parameters and locals are placed in the method's symbol table. A

method's symbol table is closed after all the statements in its body are type checked.

• When a blocknode is processed. Locals are placed in the block's symbol table. A block's symbol table is closed after all the statements in its body are type checked.

339

CS 536 Spring 2006

338

CSX Allows no Forward References

This means we can do type-checking in *one pass* over the AST. As declarations are processed, their identifiers are added to the current (innermost) symbol table. When a use of an identifier occurs, we do an ordinary block-structured lookup, always using the innermost declaration found. Hence in

```
int i = j;
int j = i;
```

the first declaration initializes i to the nearest non-local definition of j.

The second declaration initializes j to the current (local) definition of i.
