

## **CS 536 Announcements for Monday, February 26, 2024**

### **Last Time**

- Java CUP
  - specification format
  - handling precedence and associativity
  - translating lists
  - handling unary minus

### **Today**

- review for Midterm 1

### **Next Time**

- approaches to parsing
- bottom-up parsing
- CFG transformations

## **Midterm 1**

**Thursday, February 29, 7:30 – 9 pm  
S429 Chemistry**

### **Covers**

- lectures through 2/19
- programming assignments 1 & 2

### **Additional practice**

- Homeworks 0, 1, & 2
- sample midterm (esp questions 1, 3a, 3b, 4)

### **Format**

- closed-book, closed-notes
- paper and pencil/pen
- question formats
  - multiple-choice
  - short-answer
  - written questions

**Make sure to bring your student ID**

**See also Exam Information page**

## Midterm 1 Topics

### Scanning

- general :
  - what does a scanner do
  - how does it fit into the design of a compiler
- underlying model :
  - FSMs, DFAs vs NFAs
  - translating regex → NFA
  - translating NFA → DFA
- specification of a scanner :
  - regular expressions, JLex specifications\*  
\*you do not need to know all of JLex's special characters

### Context-Free Grammars

- specification of a language's syntax via a CFG
- derivations (left-most, right-most)
- parse trees
- expression grammars (precedence, associativity)
- list grammars
- ambiguous grammars
- recursive grammar (left recursive, right recursive)

### Syntax-Directed Translation

- "plain" translations
  - writing rules of the form "s1.trans ="
- being able to define translations of any types (integer, AST nodes, etc.)

## Translating a regular expression into a DFA

Example:  $ab|c$

Translate regex  $\rightarrow$  NFA (with  $\epsilon$ -transitions)

## Removing $\epsilon$ -transitions from NFAs

Let  $M$  be an NFA with  $\epsilon$ -transitions. Goal: construct  $\epsilon$ -free NFA  $M^*$  that is equivalent to  $M$

**Recall:  $\text{eclose}(s)$**  = set of all states reachable from  $s$  using 0 or more  $\epsilon$  - transitions

**Overview:**

- 1) determine  $\text{eclose}(s)$  for each state  $s \in M$
- 2) initialize  $M^*$  to  $M$
- 3) determine additional final states of  $M^*$
- 4) add edges to  $M^*$
- 5) remove  $\epsilon$ -transitions

**Final states of  $M^*$ :** If  $\text{eclose}(s)$  contains a final state in  $M$ , then  $s$  is a final state in  $M^*$

**Adding edges to  $M^*$ :** If there is edge  $s \xrightarrow{a} t$  in  $M$  ( $a \neq \epsilon$ ), then add edge  $s^* \xrightarrow{a} t^*$  in  $M^*$

- for each  $s^*$  such that  $s \in \text{eclose}(s^*)$  and
- for each  $t^* \in \text{eclose}(t)$

**Translate NFA w/  $\epsilon$ -transitions  $\rightarrow$  NFA w/o  $\epsilon$ -transitions**

## NFA w/o $\epsilon$ -transitions $\rightarrow$ DFA

## Optimize DFA

## Syntax-directed translation

### CFG

expr  $\rightarrow$  expr + term

| term

term  $\rightarrow$  term \* factor

| factor

factor  $\rightarrow$  INTLIT

| ( expr )

### Translation rules

Write a syntax-directed translation for the CFG given above so that the translation of a sequence of tokens is numeric value of the expression (i.e., the expression evaluated).
