

CS 540 Introduction to Artificial Intelligence Unsupervised Learning I

University of Wisconsin-Madison Fall 2025 Sections 1 & 2

Announcements

- Homework 2 online:
 - due tomorrow Sep 26th at 11:59 PM
- HW 3 will be released tomorrow:
 - Due on Friday Oct 3rd at 11:59PM
- Class roadmap:

Recap of Supervised/Unsupervised

Supervised learning:

- Make predictions, classify data, perform regression
- Dataset: $(\mathbf{x}_1, y_1), (\mathbf{x}_2, y_2), \dots, (\mathbf{x}_n, y_n)$

• Goal: find function $f: X \to Y$ to predict label on **new** data

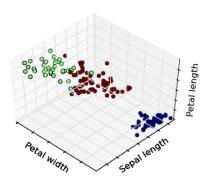

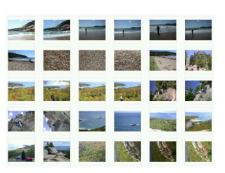

r

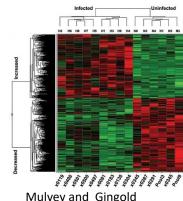

Recap of Supervised/Unsupervised

Unsupervised learning:

- No labels; generally, won't be making predictions
- Dataset: $\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_n$
- Goal: find patterns & structures that help better understand data.

Outline

- Intro to Clustering
 - Clustering Types
- Hierarchical Clustering
 - Divisive, agglomerative, linkage strategies
- Centroid-based Clustering
 - k-means

Unsupervised Learning & Clustering

- Note that clustering is just one type of unsupervised learning (UL)
 - PCA is another unsupervised algorithm
- Estimating probability distributions also UL (GANs)
- Clustering is popular & useful!

StyleGAN2 (Kerras et al '20)

Clustering Types

Several types of clustering

Hierarchical

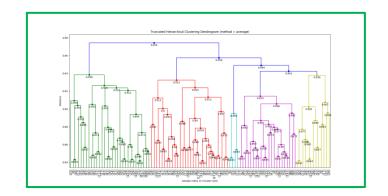

- Agglomerative
- Divisive

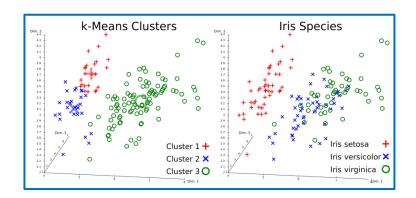

Partitional

- Center-based
- Graph-theoretic
- Spectral

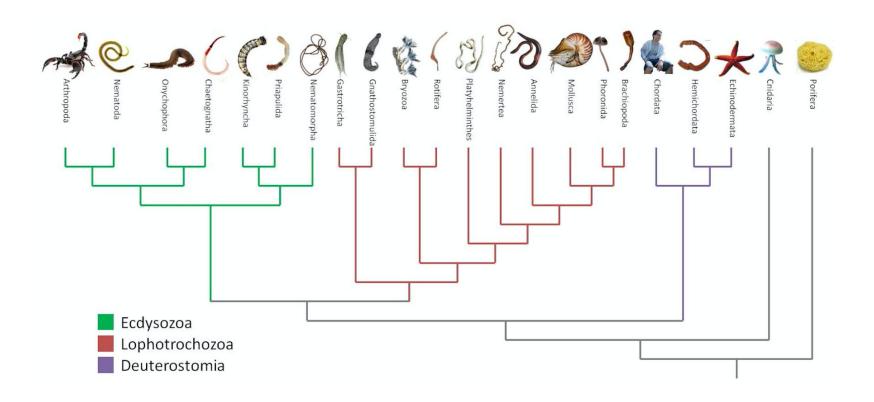

Bayesian

- Decision-based
- Nonparametric

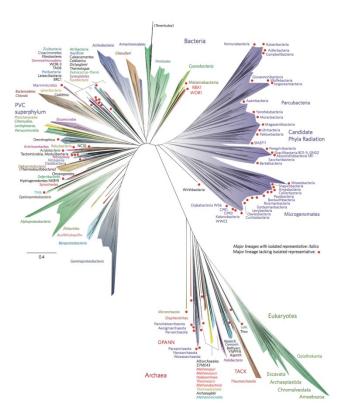

Hierarchical Clustering

Hierarchical Clustering

Basic idea: build a "hierarchy"

- Want: arrangements from specific to general
- One advantage: no need for k, number of clusters.
- Input: points. Output: a hierarchy
 - A binary tree

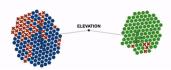

Credit: Wikipedia

Agglomerative vs Divisive

Two ways to go:

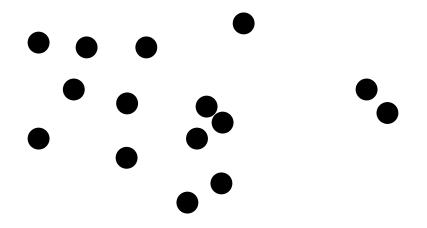

- Agglomerative: bottom up.
 - Start: each point a cluster. Progressively merge clusters

- Divisive: top down
 - Start: all points in one cluster. Progressively split clusters

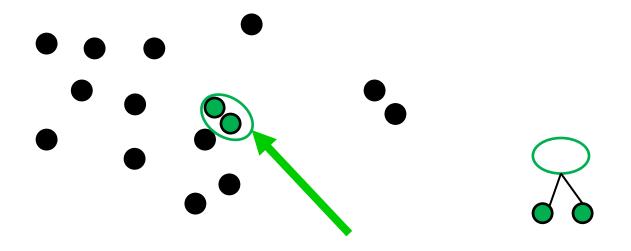

Credit: r2d3.us

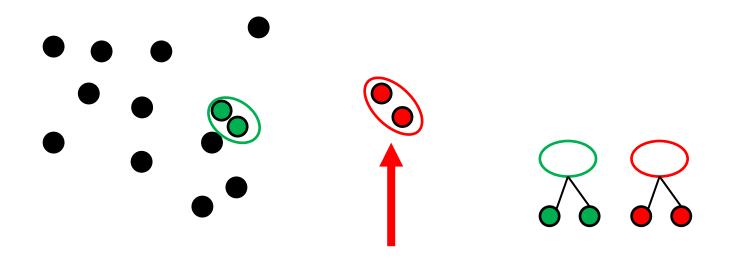

Agglomerative. Start: every point is its own cluster

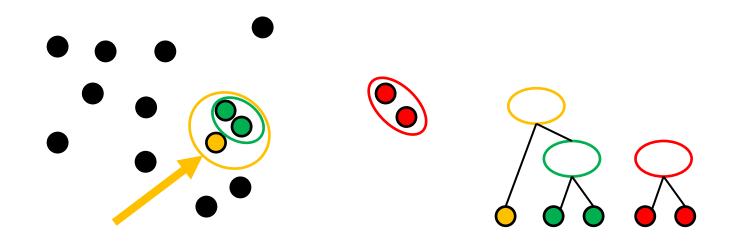

Get pair of clusters that are closest and merge

Repeat: Get pair of clusters that are closest and merge

Repeat: Get pair of clusters that are closest and merge

Merging Criteria

Merge: use closest clusters. Define closest?

• Single-linkage

$$d(A,B) = \min_{x_1 \in A, x_2 \in B} d(x_1, x_2)$$

Complete-linkage

$$d(A,B) = \max_{x_1 \in A} d(x_1, x_2)$$

Average-linkage

$$d(A,B) = \frac{1}{|A||B|} \sum_{x_1 \in A, x_2 \in B} d(x_1, x_2)$$

We'll merge using single-linkage

- 1-dimensional vectors.
- Initial: all points are clusters

We'll merge using single-linkage

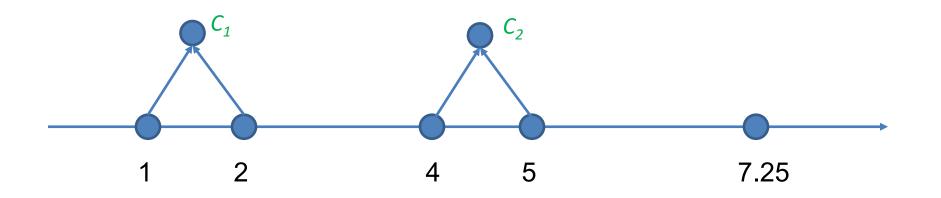

$$d(C_1, \{4\}) = d(2, 4) = 2$$

$$d(\{4\}, \{5\}) = d(4, 5) = 1$$
1 2 4 5 7.25

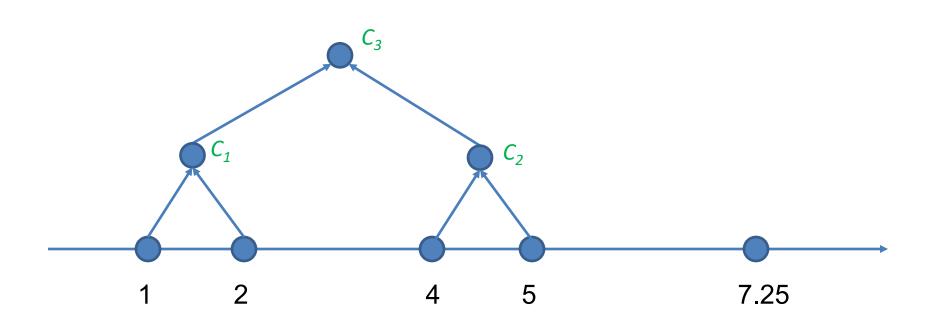

Continue...

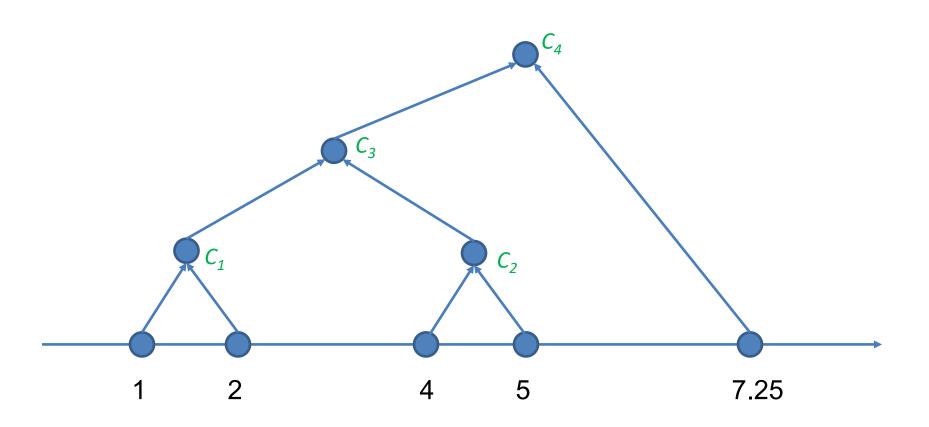

$$d(C_1, C_2) = d(2, 4) = 2$$

 $d(C_2, \{7.25\}) = d(5, 7.25) = 2.25$

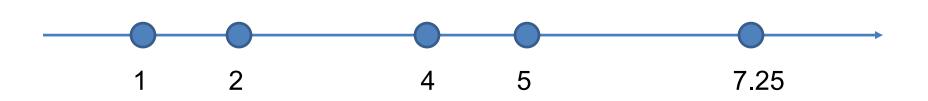

Continue...

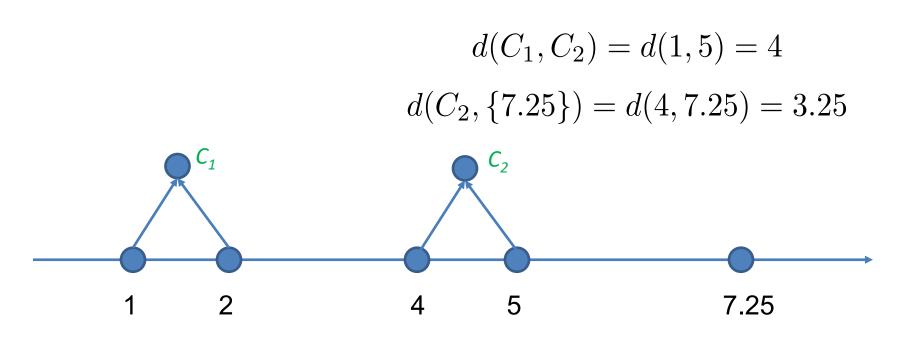

We'll merge using complete-linkage

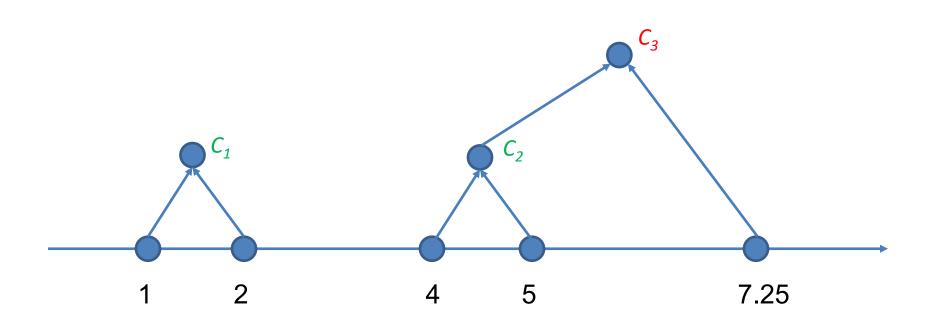

- 1-dimensional vectors.
- Initial: all points are clusters

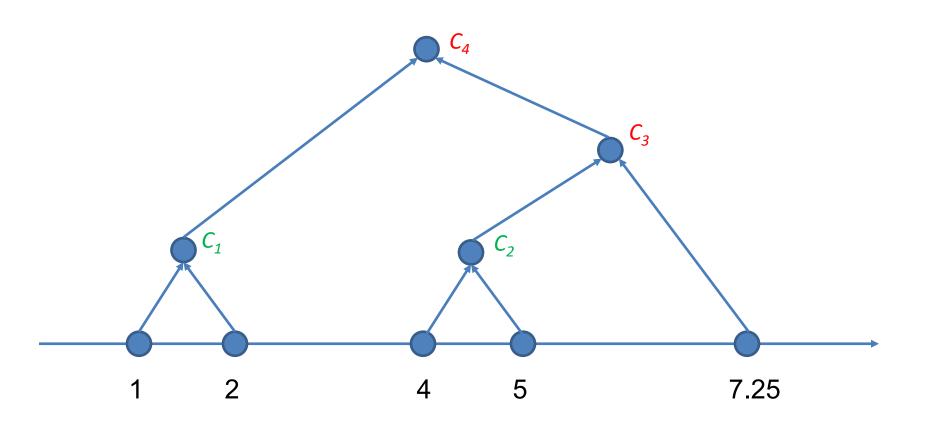

Beginning is the same...

Now we diverge:

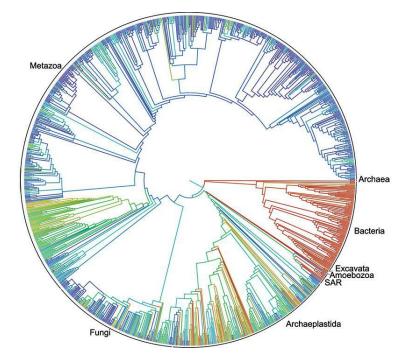

When to Stop?

No simple answer:

 Use the binary tree (a dendogram)

 Cut at different levels (get different heights/depths)

http://opentreeoflife.org/

Q 1.1: Let's do hierarchical clustering for two clusters with average linkage on the dataset below. What are the clusters?

- A. {1}, {2,4,5,7.25}
- B. {1,2}, {4, 5, 7.25}
- C. {1,2,4}, {5, 7.25}
- D. {1,2,4,5}, {7.25}

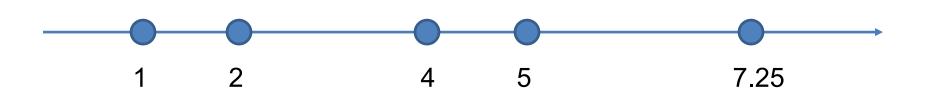

Q 1.1: Let's do hierarchical clustering for two clusters with average linkage on the dataset below. What are the clusters?

```
• A. {1}, {2,4,5,7.25}
```

- B. {1,2}, {4, 5, 7.25}
- C. {1,2,4}, {5, 7.25}
- D. {1,2,4,5}, {7.25}

```
Iteration 1: merge 1 and 2
Iteration 2: merge 4 and 5
Iteration 3: Now we have clusters \{1,2\}, \{4,5\}, \{7.25\}.
distance(\{1,2\}, \{4,5\}) = 3
distance(\{4,5\}, \{7.25\}) = 2.75
distance(\{1,2\}, \{7.25\}) is clearly larger than the above two.
So average linkage will merge \{4,5\} and \{7.25\}
```

Q 1.2: If we do hierarchical clustering on n points, the maximum depth of the resulting tree is

- A. 2
- B. log *n*
- C. n/2
- D. *n*-1

Q 1.2: If we do hierarchical clustering on n points, the maximum depth of the resulting tree is

- A. 2
- B. log *n*
- C. n/2
- D. *n*-1

```
Denote the points as x_1, x_2, ..., x_n
Suppose:
in iteration 1, we merge points x_1 and x_2
in iteration 2, we merge {x_1, x_2} with x_3
...
in iteration t, we merge {x_1, x_2, ..., x_t} with x_{t+1}
...
in iteration n-1, we merge {x_1, x_{n-1}} with x_n
```

Then we will get a tree with depth n-1.

Center-based Clustering

- k-means is an example of a partitional, center-based clustering algorithm.
- Specify a desired number of clusters, k; run k-means to find k clusters.

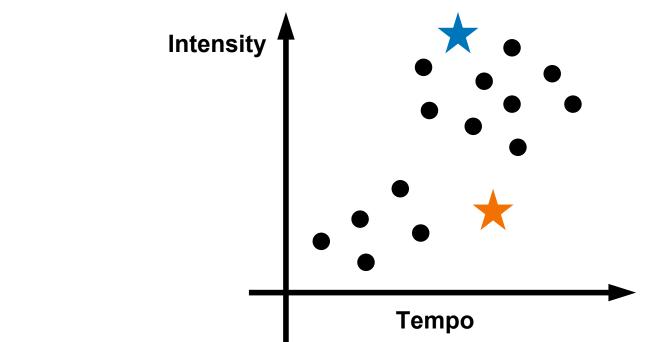

Very popular clustering method

$$x_1, x_2, \ldots, x_n$$

 Input: a dataset, and assume the number of clusters k is given

Step 1: Randomly picking 2 positions as initial cluster centers

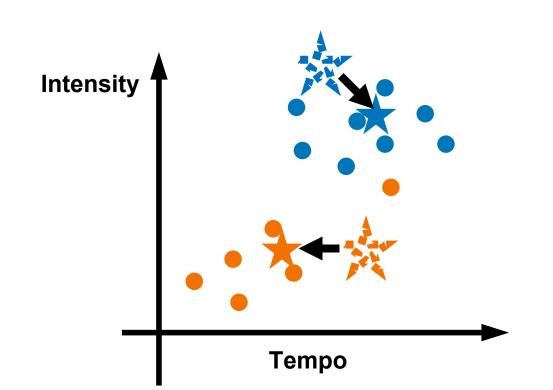

(not necessarily a data point)

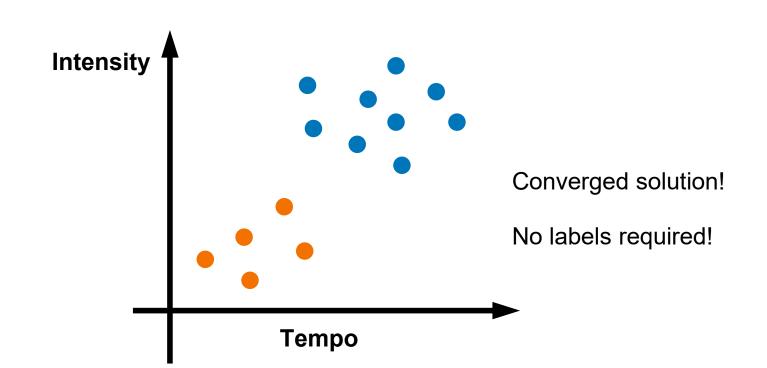

Step 2: for each point x, determine its cluster: find the closest center in Euclidean space

Step 3: update all cluster centers as the centroids

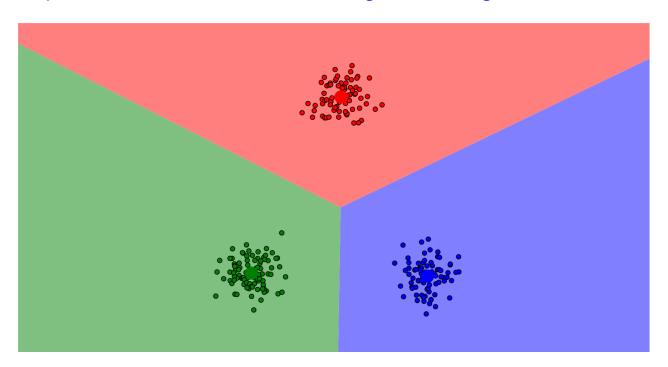

K-means clustering Repeat step 2 & 3 until convergence

K-means clustering: A demo

https://www.naftaliharris.com/blog/visualizing-k-means-clustering/

K-means algorithm

- Input: $x_1, x_2, ..., x_n, k$
- Step 1: select k cluster centers $c_1, c_2, ..., c_k$
- Step 2: for each point x_i , assign it to the closest center in Euclidean distance:

$$y(x_i) = \operatorname{argmin}_i ||x_i - c_i||$$

Step 3: update all cluster centers as the centroids:

$$c_j = \frac{\sum_{x:y(x)=j} x}{\sum_{x:y(x)=j} 1}$$

Repeat Step 2 and 3 until cluster centers no longer change

- What is k-means trying to optimize?
- Will k-means stop (converge)?
- Will it find a global or local optimum?
- How to pick starting cluster centers?
- How many clusters should we use?

The optimization problem of k-means

What is k-means trying to optimize?

$$\min_{c,y} \sum_{i=1}^{N} ||x_i - c_{y(x_i)}||^2$$

Will k-means stop (converge)? Yes

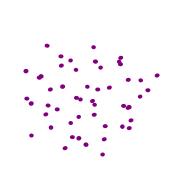

Given a fixed dataset and a fixed number of clusters, there are only a **finite number of ways** to assign data points to clusters.

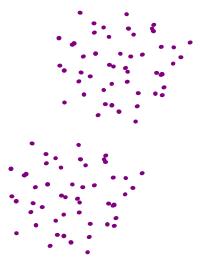

Each iteration consists of:

- Assignment Step: Assign each data point to the closest centroid.
- Update Step: Recompute centroids as the mean of assigned points.

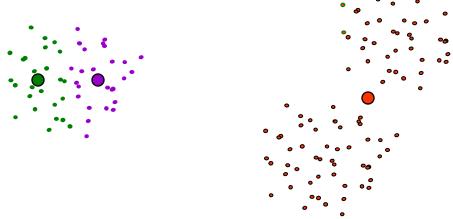

These steps **always reduce or keep the same** the objective function (sum of squared distance), ensuring termination.

Will it find a global or local optimum? (sadly no guarantee)

Will it find a global or local optimum? (sadly no guarantee)

How to pick starting cluster centers?

- Randomly
- Kmeans++ (improving initialization)

How many clusters should we use?

- Difficult problem
- Domain knowledge
- Elbow Method
 - Compute the within-cluster sum of squares (WCSS) for different values of k.
 - Plot WCSS vs. k and look for the elbow point where the reduction in WCSS slows down. The optimal k is typically at this elbow.

Q 2.1: You have seven 2-dimensional points. You run 3-means on it, with initial clusters

$$C_1 = \{(2,2), (4,4), (6,6)\}, C_2 = \{(0,4), (4,0)\}, C_3 = \{(5,5), (9,9)\}$$

Cluster centroids are updated to?

- A. C₁: (4,4), C₂: (2,2), C₃: (7,7)
- B. C₁: (6,6), C₂: (4,4), C₃: (9,9)
- C. C₁: (2,2), C₂: (0,0), C₃: (5,5)
- D. C₁: (2,6), C₂: (0,4), C₃: (5,9)

Q 2.1: You have seven 2-dimensional points. You run 3-means on it, with initial clusters

$$C_1 = \{(2,2), (4,4), (6,6)\}, C_2 = \{(0,4), (4,0)\}, C_3 = \{(5,5), (9,9)\}$$

Cluster centroids are updated to?

- A. C₁: (4,4), C₂: (2,2), C₃: (7,7)
- B. C₁: (6,6), C₂: (4,4), C₃: (9,9)
- C. C₁: (2,2), C₂: (0,0), C₃: (5,5)
- D. C₁: (2,6), C₂: (0,4), C₃: (5,9)

The average of points in C1 is (4,4).

The average of points in C2 is (2,2).

The average of points in C3 is (7,7).

Q 2.2: We are running 3-means again. We have 3 centers, C_1 (0,1), C_2 , (2,1), C_3 (-1,2). Which cluster assignment is possible for the points (1,1) and (-1,1), respectively? Ties are broken arbitrarily:

- A. Only (i)
- B. Only (ii) and (iii)
- C. Only (i) and (iii)
- D. All of them

Q 2.2: We are running 3-means again. We have 3 centers, C_1 (0,1), C_2 , (2,1), C_3 (-1,2). Which cluster assignment is possible for the points (1,1) and (-1,1), respectively? Ties are broken arbitrarily:

- A. Only (i)
- B. Only (ii) and (iii)
- C. Only (i) and (iii)
- · D. All of them

For the point (1,1): square-Euclidean-distance to C1 is 1, to C2 is 1, to C3 is 5
So it can be assigned to C1 or C2

For the point (-1,1): square-Euclidean-distance to C1 is 1, to C2 is 9, to C3 is 1
So it can be assigned to C1 or C3

Q 2.3: If we run K-means clustering twice with random starting cluster centers, are we guaranteed to get same clustering results? Does K-means always converge?

- A. Yes, Yes
- B. No, Yes
- C. Yes, No
- D. No, No

Q 2.3: If we run K-means clustering twice with random starting cluster centers, are we guaranteed to get same clustering results? Does K-means always converge?

- A. Yes, Yes
- B. No, Yes
- C. Yes, No
- D. No, No

The clustering from k-means will depend on the initialization. Different initialization can lead to different outcomes.

K-means will always converge on a finite set of data points:

- 1. There are finite number of possible partitions of the points
- 2. The assignment and update steps of each iteration will only decrease the sum of the distances from points to their corresponding centers.
- 3. If it run forever without convergence, it will revisit the same partition, which is contradictory to item 2.

Thanks!
