

CS 540 Introduction to Artificial Intelligence Reinforcement Learning II

University of Wisconsin-Madison Spring 2025

Announcements

- Homework:
 - HW9 due on Wednesday April 23rd at 11:59 PM
- Final Exam:
 - May 7th 07:45 09:45 AM
 - Lecture 001 (MW 14:30 15:45): S429 Chemistry Building
 - Lecture 002 (TR 11:00 12:15): 1220 Microbial Sciences
 - Lecture 003 (TR 16:00 17:15): B10 Ingraham Hall
 - Students with Mc Burney accommodations or alternate requests will be notified about the exam time and location.
 - More information coming soon!
- Course evaluation
- Class roadmap:

Reinforcement Learning II

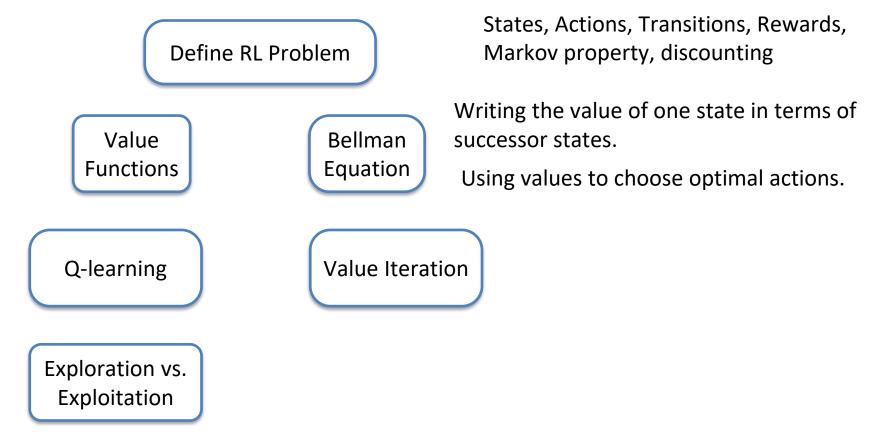

Advanced Search

Ethics and Trust in AI

Outline

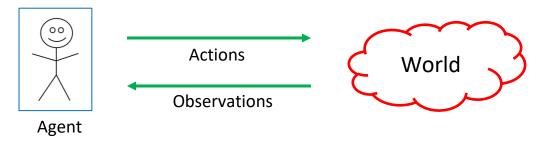

- Review of reinforcement learning setting.
 - MDPs, value functions
- Bellman equations and dynamic programming
- From dynamic programming to Q-learning

Key Ideas in Reinforcement Learning

Back to Our General Model

We have an **agent interacting** with the **world**

- Agent receives a reward based on state of the world
 - Goal: maximize reward / utility (\$\$\$)
 - Note: data consists of actions & observations
 - Compare to unsupervised learning and supervised learning

Markov Decision Process (MDP)

The formal mathematical model:

- State set S. Initial state s_{0.} Action set A
- State transition model: $P(s_{t+1}|s_t, a_t)$
 - Markov assumption: transition probability only depends on s_t and a_t , and not previous actions or states.
- Reward function: **r**(s_t)
- Policy: $\pi(s): S \to A$, action to take at a particular state.

$$s_0 \xrightarrow{a_0} s_1 \xrightarrow{a_1} s_2 \xrightarrow{a_2} \dots$$

Defining the Optimal Policy

For policy π , **expected utility** over all possible state sequences from s_0 produced by following that policy:

$$V^{\pi}(s_0) = \sum P(\text{sequence})U(\text{sequence})$$

sequences starting from s₀

Called the value function (for π , s_0)

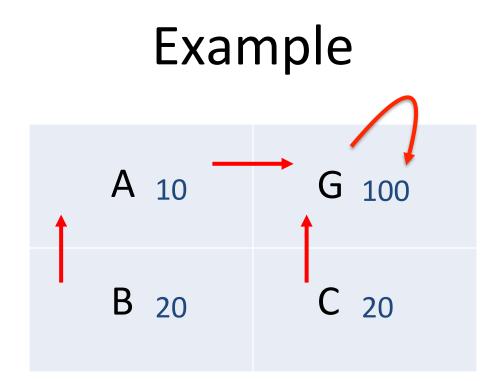

Discounting Rewards

One issue: these are infinite series. **Convergence**?

• Solution

$$U(\mathbf{s}_0, \mathbf{s}_1 \dots) = r(\mathbf{s}_0) + \gamma r(\mathbf{s}_1) + \gamma^2 r(\mathbf{s}_2) + \dots = \sum_{t \ge 0} \gamma^t r(\mathbf{s}_t)$$

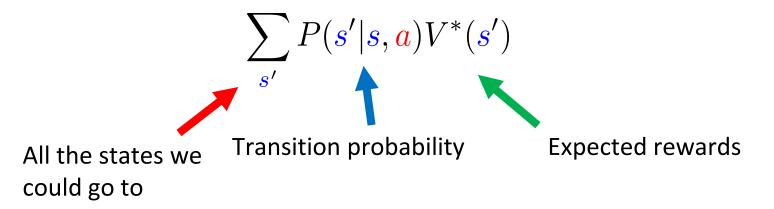

- Discount factor γ between 0 and 1
 - Set according to how important present is VS future
 - Note: has to be less than 1 for convergence

Deterministic transitions; $\gamma = 0.8$; policy shown with red arrows.

Values and Policies

- Now that $V^{\pi}(s_0)$ is defined what *a* should we take?
 - First, set V*(s) to be expected utility for **optimal** policy from s
 - What's the expected utility of an action?
 - Specifically, action a in state s?

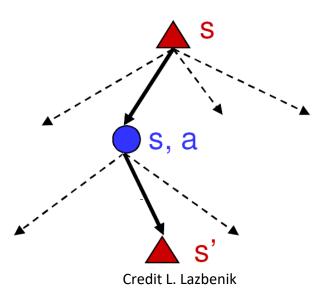

Obtaining the Optimal Policy

Assume, we know the expected utility of an action.

• So, to get the optimal policy, compute

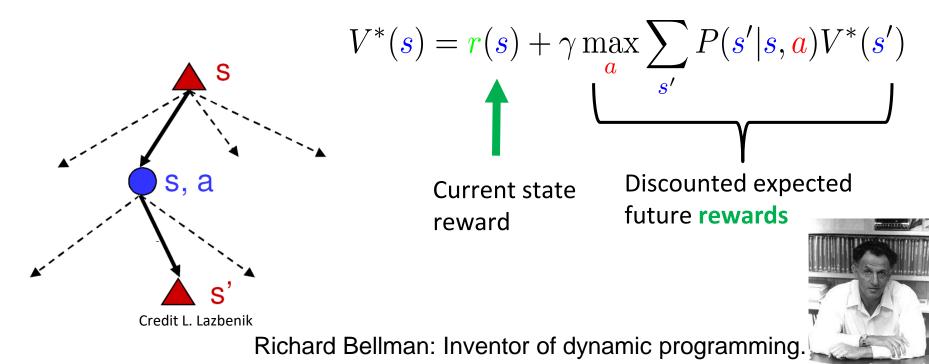

$$\pi^{*}(s) = \operatorname{argmax}_{a} \sum_{s'} P(s'|s, a) V^{*}(s')$$

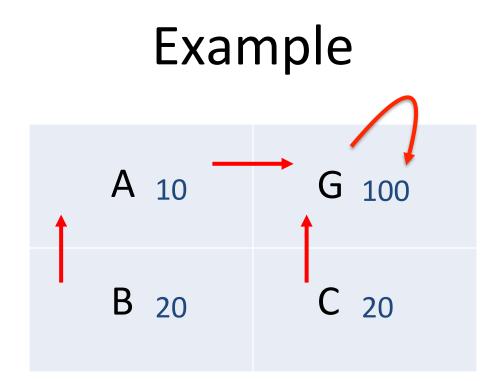

All the states we transition Expected could go to probability rewards

Bellman Equations

Let's walk over one step for the value function:

Deterministic transitions; $\gamma = 0.8$; policy shown with red arrows.

Value Iteration

- **Q**: how do we find $V^*(s)$?
- Why do we want it? Can use it to get the best policy
- Know: reward **r**(**s**), transition probability P(**s**' | **s**,**a**)
- Also know V*(s) satisfies Bellman equation: $V^*(s) = r(s) + \gamma \max_{a} \sum_{s'} P(s'|s, a) V^*(s')$

A: Use the property. Start with $V_0(s)=0$. Then, update

$$V_{i+1}(s) = r(s) + \gamma \max_{a} \sum_{s'} P(s'|s, a) V_i(s')$$

Q-Learning

- Our next reinforcement learning algorithm.
- Does not require knowing r or P. Learn from data of the form:{(s_t, a_t, r_t, s_{t+1})}.
- Learns an action-value function Q*(s,a) that tells us the expected value of taking a in state s.

• Note:
$$V^*(s) = \max_{a} Q^*(s, a)$$
.

• Optimal policy is formed as $\pi^*(s) = \arg\max_a Q^*(s, a)$

The Q*(s,a) function

• Starting from state s, perform (perhaps suboptimal) action *a*. THEN follow the optimal policy

$$Q^{*}(s,a) = r(s) + \gamma \sum_{s'} P(s'|s,a) V^{*}(s')$$

• Equivalent to

$$Q^{*}(s,a) = r(s) + \gamma \sum_{s'} P(s'|s,a) \max_{a'} Q^{*}(s',a')$$

Q-Learning Iteration

How do we get Q(*s*,*a*)?

Iterative procedure

$$Q(s_t, a_t) \leftarrow Q(s_t, a_t) + \alpha [r(s_t) + \gamma \max_{a} Q(s_{t+1}, a) - Q(s_t, a_t)]$$

Learning rate

Idea: combine old value and new estimate of future value. Note: We are using a policy to take actions; based on the estimated Q!

Q-Learning

Estimate $Q^{*}(s,a)$ from data { (s_t, a_t, r_t, s_{t+1}) }:

- 1. Initialize Q(.,.) arbitrarily (eg all zeros)
 - 1. Except terminal states Q(s_{terminal},.)=0
- 2. Iterate over data until Q(.,.) converges:

$$Q(s_t, a_t) \leftarrow (1 - \alpha)Q(s_t, a_t) + \alpha(r_t + \gamma \max_b Q(s_{t+1}, b))$$

Learning rate

Exploration Vs. Exploitation

General question!

- **Exploration:** take an action with unknown consequences
 - Pros:
 - Get a more accurate model of the environment
 - Discover higher-reward states than the ones found so far
 - Cons:
 - When exploring, not maximizing your utility
 - Something bad might happen
- Exploitation: go with the best strategy found so far
 - Pros:
 - Maximize reward as reflected in the current utility estimates
 - Avoid bad stuff
 - Cons:
 - Might prevent you from discovering the true optimal strategy

Q-Learning: ε-Greedy Behavior Policy

Getting data with both **exploration and exploitation**

 With probability ε, take a random action; else the action with the highest (current) Q(s,a) value.

$$a = \begin{cases} \operatorname{argmax}_{a \in A} Q(s, a) & \operatorname{uniform}(0, 1) > \epsilon \\ \operatorname{random} a \in A & \operatorname{otherwise} \end{cases}$$

Q-learning Algorithm

Input: step size α , exploration probability ϵ

- 1. set Q(s,a) = 0 for all s, a.
- 2. For each episode:
- 3. Get initial state s.
- 4. While (s not a terminal state):

Explore: take action to see what happens.

5. Perform $a = \epsilon$ -greedy(Q, s), receive r, s'

6.
$$Q(s,a) = (1-\alpha)Q(s,a) + \alpha(r + \gamma \max_{a'}Q(s',a'))$$

Update action-value based on result.

8. End While

7. $s \leftarrow s'$

9. End For

Q-Learning: SARSA

An alternative update rule:

• Just use the next action, no max over actions:

$$Q(\mathbf{s}_t, \mathbf{a}_t) \leftarrow Q(\mathbf{s}_t, \mathbf{a}_t) + \alpha [r(\mathbf{s}_t) + \gamma Q(\mathbf{s}_{t+1}, \mathbf{a}_{t+1}) - Q(\mathbf{s}_t, \mathbf{a}_t)]$$

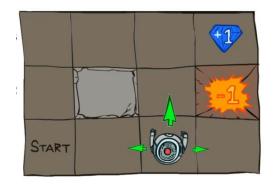

Learning rate

- Called state-action-reward-state-action (SARSA)
- Can use with epsilon-greedy policy

Q-Learning Details

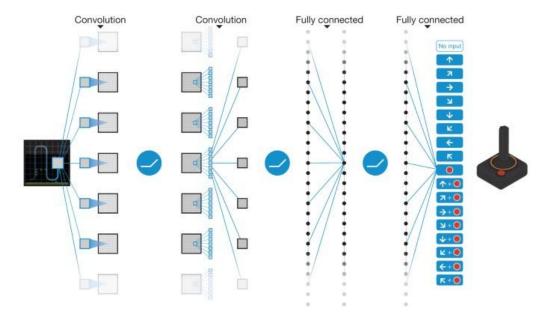

Note: if we have a **terminal** state, the process ends

- An **episode**: a sequence of states ending at a terminal state
- Want to run on many episodes
- Slightly different Q-update for terminal states

Deep Q-Learning

How do we get Q(*s*,*a*) with a large number of states?

Mnih et al, "Human-level control through deep reinforcement learning"

Deep Q-Learning

How do we get Q(*s*,*a*) with a large number of states?

- Deep Q-learning uses a neural network to approximate Q(s,a)
 - Let $Q_{\theta}: S \times A \to \mathbb{R}$ be the neural network with weights and biases denoted θ .
- Training is similar to supervised regression:
 - (s, a) as input and $y = r(s) + \gamma \max_{a'} Q_{\theta}(s', a')$ as label.
 - Note that output of the neural network is used in the label.
 - Loss function: $\mathcal{L}(\theta) = (y Q_{\theta}(s, a))^2$

Break & Quiz

Q 2.2 For Q learning to converge to the true Q function, we must

- A. Visit every state and try every action infinitely often.
- B. Perform at least 20,000 iterations.
- C. Re-start with different random initial table values.
- D. Prioritize exploitation over exploration.

Break & Quiz

Q 2.2 For Q learning to converge to the true Q function, we must

- A. Visit every state and try every action infinitely often
- B. Perform at least 20,000 iterations.
- C. Re-start with different random initial table values.
- D. Prioritize exploitation over exploration.

Break & Quiz

Q 2.2 For Q learning to converge to the true Q function, we must

- A. Visit every state and try every action infinitely often.
- B. Perform at least 20,000 iterations. (No: this is dependent on the particular problem, not a general constant).
- C. Re-start with different random initial table values. (No: this is not necessary in general).
- D. Prioritize exploitation over exploration. (No: insufficient exploration means potentially unupdated state action pairs).

Summary of RL

- Reinforcement learning setup
- Mathematical formulation: MDP
- Value functions & the Bellman equation
- Value iteration
- Q-learning
