21. Swapping: Mechanisms

Operating System: Three Easy Pieces

Beyond Physical Memory: Mechanisms

- **•** Require an additional level in the memory hierarchy.
 - OS need a place to stash away portions of address space that currently aren't in great demand.
 - In modern systems, this role is usually served by a hard disk drive

Memory Hierarchy in modern system

Single large address for a process

 Always need to first arrange for the code or data to be in memory when before calling a function or accessing data.

- **D** To Beyond just a single process.
 - The addition of swap space allows the OS to support the illusion of a large virtual memory for multiple concurrently-running process

- **n** Reserve some space on the disk for moving pages back and forth.
- OS need to remember to the swap space, in page-sized unit

		PFN	0	F	PFN 1	PFN 2		PFN	3		
	Physical Memory	Proc [VPN	Proc 0 [VPN 0]		Proc 1 /PN 2]	Proc 1 [VPN 3]		Proc 2 [VPN 0]			
	Block 0	Block 1	Bloc	:k 2	Block 3	Block 4	I	Block 5	Block	< 6	Block 7
Swap Space	Proc 0 [VPN 1]	Proc 0 [VPN 2]	[Fre	e]	Proc 1 [VPN 0]	Proc 1 [VPN 1]	[Proc 3 VPN 0]	Proc [VPN	2 1]	Proc 3 [VPN 1]

Physical Memory and Swap Space

Present Bit

- Add some machinery higher up in the system in order to support swapping pages to and from the disk.
 - When the hardware looks in the PTE, it may find that the page is not present in physical memory.

Value	Meaning			
1	page is present in physical memory			
0	The page is not in memory but rather on disk.			

What If Memory Is Full ?

- The OS like to page out pages to make room for the new pages the OS is about to bring in.
 - The process of picking a page to kick out, or replace is known as pagereplacement policy

The Page Fault

- Accessing page that is not in physical memory.
 - If a page is not present and has been swapped disk, the OS need to swap the page into memory in order to service the page fault.

Page Fault Control Flow

D PTE used for data such as the PFN of the page for a disk address.

Page Fault Control Flow – Hardware

1:	VPN = (VirtualAddress & VPN_MASK) >> SHIFT
2:	(Success, TlbEntry) = TLB_Lookup(VPN)
3:	if (Success == True) // TLB Hit
4:	<pre>if (CanAccess(TlbEntry.ProtectBits) == True)</pre>
5:	Offset = VirtualAddress & OFFSET_MASK
6:	PhysAddr = (TlbEntry.PFN << SHIFT) Offset
7:	Register = AccessMemory(PhysAddr)
8:	<pre>else RaiseException(PROTECTION_FAULT)</pre>

Page Fault Control Flow – Hardware

9:	else // TLB Miss
10:	PTEAddr = PTBR + (VPN * sizeof(PTE))
11:	PTE = AccessMemory (PTEAddr)
12:	<pre>if (PTE.Valid == False)</pre>
13:	RaiseException(SEGMENTATION_FAULT)
14:	else
15:	<pre>if (CanAccess(PTE.ProtectBits) == False)</pre>
16:	RaiseException(PROTECTION_FAULT)
17:	<pre>else if (PTE.Present == True)</pre>
18:	// assuming hardware-managed TLB
19:	TLB_Insert(VPN, PTE.PFN, PTE.ProtectBits)
20:	RetryInstruction()
21:	<pre>else if (PTE.Present == False)</pre>
22:	RaiseException(PAGE_FAULT)

1:	<pre>PFN = FindFreePhysicalPage()</pre>
2:	<pre>if (PFN == -1) // no free page found</pre>
3:	<pre>PFN = EvictPage() // run replacement algorithm</pre>
4:	<pre>DiskRead(PTE.DiskAddr, pfn) // sleep (waiting for I/O)</pre>
5:	<pre>PTE.present = True // update page table with present</pre>
6:	PTE.PFN = PFN // bit and translation (PFN)
7:	RetryInstruction() // retry instruction

- The OS must find a physical frame for the soon-be-faulted-in page to reside within.
- If there is no such page, waiting for the replacement algorithm to run and kick some pages out of memory.

When Replacements Really Occur

- OS waits until memory is entirely full, and only then replaces a page to make room for some other page
 - This is a little bit unrealistic, and there are many reason for the OS to keep a small portion of memory free more proactively.

- **D** Swap Daemon, Page Daemon
 - There are fewer than LW pages available, a background thread that is responsible for freeing memory runs.
 - The thread evicts pages until there are HW pages available.
