Outline

- 2 Generalized Linear Models(GLMs or GLIM)
- Independence Screening with MMLE
- An Exponential Bound for QMLE (a more general result)
- 5 Sure Screening Properties with MMLE
 - Population Aspects
 - Sampling Aspects: uniform convergence and sure screening
 - Controlling False Selection Rates
- 6 A Likelihood Ratio Screening
- 7 Numerical Results
 - 8 Conclusion Remarks

- high dimensional data analysis
 - $p \rightarrow p_n$
 - $p = O(n^a)$ for some a > 0
 - $\log p = O(n^a)$ for some a > 0, which is NP-dimensionality, or loosely ultra high dimensionality
- variable/model selection: approach 1 (penalized pseudo-likelihood)
 - bridge regression (1993), LASSO (1996), SCAD (2001), Dantzig selector (2007), and their variants.
 - theoretical studies on persistency, consistency and oracle properties.
 - limitations: may not perform well in ultra high dimensional setting due to the simultaneous challenges of computational expediency, statistical accuracy and algorithmic stability (Fan et al. 2009)

- variable/model selection: approach 2
 - Fan and Lv (2008): SIS method
 - limitations: only restricts to the ordinary linear model, and technical arguments can not be easily extended
 - Huang et al. (2008): based on marginal bridge regression
 - similar limitations
 - SIS in GLMs: Fan et al. (2009), Fan and Song (2010)
 - Hall et al. (2009): used a different marginal utility, derived from an empirical likelihood point of view
 - Hall and Miller (2009): proposed a generalized correlation ranking, which allows nonlinear regression
 - Wang (2009): Forward Regression
 - Fan and his colleagues (2010+): nonparametric IS for additive model, penalized composite quasi-likelihood, SIS for Cox's proportional hazards model, ...

- In this paper, rank the maximum marginal likelihood estimator (MMLE) or maximum marginal likelihood, for GLMs
- An important extension of SIS in Fan and Lv (2008)
- Advantages: a new framework, which does not depend on the normality assumption even in the linear model setting; can be applied to possibly other models, like Cox model; can easily be applied to the generalized correlation ranking and other rankings based on a group of marginal variables.
- The two methods, ranking MMLE or maximum marginal likelihood, are equivalent in terms of sure screening properties.

 - 8 Conclusion Remarks

assume the pdf of Y is

$$f_{\mathsf{Y}}(\mathsf{y};\theta) = \exp\{\mathsf{y}\theta - \mathsf{b}(\theta) + \mathsf{c}(\mathsf{y})\}$$

- only model the mean regression, do not consider the dispersion parameter
- the model to be considered is

$$E(Y|\boldsymbol{X} = \boldsymbol{x}) = b'(\theta(\boldsymbol{x})) = g^{-1}(\sum_{j=0}^{p_n} \beta_j x_j)$$

<日 > < 同 > < 目 > < 目 > < 目 > < 目 > < 0 < 0</p>

- focus on the canonical link function for simplicity of presentation
- assume $EX_j = 0, EX_j^2 = 1, j = 1, ..., p_n$.

- Controlling False Selection Rates
- 6 A Likelihood Ratio Screening
- 7 Numerical Results
 - 8 Conclusion Remarks

- assume the true sparse model is $\mathcal{M}_{\star} = \{1 \leq j \leq p_n : \beta_j^{\star} \neq 0\}$, where $\beta^{\star} = (\beta_0^{\star}, \beta_1^{\star}, ..., \beta_{p_n}^{\star})$ denotes the true value, and $s_n = |\mathcal{M}_{\star}|$
- the maximum marginal likelihood estimator is defined as

$$\hat{eta}_j^{M} = (\hat{eta}_{j,0}^{M}, \hat{eta}_j^{M}) = argmin_{eta_0, eta_j} \mathbb{P}_n l(eta_0 + eta_j X_j, \mathsf{Y})$$

 similarly, define the population version of the minimizer of the componentwise regression

$$eta_j^{\mathcal{M}} = (eta_{j,0}^{\mathcal{M}},eta_j^{\mathcal{M}}) = \textit{argmin}_{eta_0,eta_j}\textit{El}(eta_0+eta_jX_j,\mathsf{Y}),$$

where *E* denotes the expectation under the true model

variables selected are Â_{γn} = {1 ≤ j ≤ p_n : |β̂^M_j| ≥ γ_n}, where γ_n is a predefined threshold value

- Controlling False Selection Rates
- 6 A Likelihood Ratio Screening
- 7 Numerical Results
 - 8 Conclusion Remarks

- consider i.i.d. data $\{X_i, Y_i\}$
- a regression model for **X** and **Y** is assumed with quasi-likelihood function $-I(\mathbf{X}^T \boldsymbol{\beta}, \mathbf{Y})$
- define $\beta_0 = \operatorname{argmin}_{\beta} EI(\mathbf{X}^T \beta, Y)$ to be the population parameter
- define $\hat{\boldsymbol{\beta}} = \operatorname{argmin}_{\boldsymbol{\beta}} \mathbb{P}_{n} I(\boldsymbol{X}^{T} \boldsymbol{\beta}, \mathbf{Y})$, which is QMLE
- assume that β_0 is an interior point of a sufficient large, compact and convex set $B \in R^q$

(日) (日) (日) (日) (日) (日) (日) (日)

A. The Fisher information

$$I(\boldsymbol{\beta}) = \boldsymbol{E}\{[\frac{\partial}{\partial \boldsymbol{\beta}} I(\boldsymbol{X}^{T} \boldsymbol{\beta}, \boldsymbol{Y})][\frac{\partial}{\partial \boldsymbol{\beta}} I(\boldsymbol{X}^{T} \boldsymbol{\beta}, \boldsymbol{Y})]^{T}\}$$

◆□▶ ◆□▶ ◆□▶ ◆□▶ □ のQで

is finite and positive definite at $\beta = \beta_0$. Moreover, $\|I(\beta)\|_{\boldsymbol{B}} = \sup_{\beta \in \boldsymbol{B}, \|\boldsymbol{x}\|=1} \|I(\beta)^{1/2} \boldsymbol{x}\|$ exists.

Regularity Conditions

B. The function $I(\mathbf{x}^T \boldsymbol{\beta}, \mathbf{y})$ satisfies the Lipschitz property with positive constant k_n :

$$|l(\mathbf{x}^{T}\boldsymbol{\beta}, \mathbf{y}) - l(\mathbf{x}^{T}\boldsymbol{\beta}', \mathbf{y})| l_{n}(\mathbf{x}, \mathbf{y}) \leq k_{n}|\mathbf{x}^{T}\boldsymbol{\beta} - \mathbf{x}^{T}\boldsymbol{\beta}'| l_{n}(\mathbf{x}, \mathbf{y}),$$

for $\beta, \beta' \in \mathbf{B}$, where $I_n(\mathbf{x}, \mathbf{y}) = I((\mathbf{x}, \mathbf{y}) \in \Omega_n)$ with $\Omega_n = \{(\mathbf{x}, \mathbf{y}) : \|\mathbf{x}\|_{\infty} \le K_n, |\mathbf{y}| \le K_n^*\}$, for some sufficiently large positive constants K_n and K_n^* . In addition, there exists a sufficiently large constant *C* such that with $b_n = Ck_n V_n^{-1} (q/n)^{1/2}$ and V_n given in condition C,

 $\sup_{\boldsymbol{\beta}\in\boldsymbol{B}, \|\boldsymbol{\beta}-\boldsymbol{\beta}_0\|\leq b_n} |\boldsymbol{E}[\boldsymbol{I}(\boldsymbol{X}^T\boldsymbol{\beta}, \boldsymbol{Y}) - \boldsymbol{I}(\boldsymbol{X}^T\boldsymbol{\beta}_0, \boldsymbol{Y})](1 - \boldsymbol{I}_n(\boldsymbol{X}, \boldsymbol{Y}))| \leq o(q/n).$

where V_n is the constant given in condition C.

C. The function $I(\mathbf{X}^T \boldsymbol{\beta}, \mathbf{Y})$ is convex in $\boldsymbol{\beta}$, satisfying $E[I(\mathbf{X}^T \boldsymbol{\beta}, \mathbf{Y}) - I(\mathbf{X}^T \boldsymbol{\beta}_0, \mathbf{Y})] \ge V_n \|\boldsymbol{\beta} - \boldsymbol{\beta}_0\|^2$, for all $\|\boldsymbol{\beta} - \boldsymbol{\beta}_0\| \le b_n$ and some positive constants V_n .

Theorem

Theorem 1. Under conditions A-C, it holds that for any t > 0,

 $P(\sqrt{n}\|\hat{\beta}-\beta_0\| \geq 16k_n(1+t)/V_n) \leq \exp(-2t^2/K_n^2) + nP(\Omega_n^c).$

(ロ) (同) (三) (三) (三) (三) (○) (○)

Lemma

Lemma 2. (Symmetrization,Lemma 2.3.1,van der Vaart and Wellner,1996) Let $Z_1, ..., Z_n$ be independent random variables with values in \mathcal{Z} and \mathcal{F} is a class of real valued functions on \mathcal{Z} . Then

$$E\{\sup_{f\in\mathcal{F}}|(\mathbb{P}_n-P)f(Z)|\}\leq 2E\{\sup_{f\in\mathcal{F}}|\mathbb{P}_n\varepsilon f(Z)|\},$$

where $\varepsilon_1, ..., \varepsilon_n$ be a Rademacher sequence (i.e., i.i.d. sequence taking values ± 1 with probability 1/2) independent of $Z_1, ..., Z_n$ and Pf(Z) = Ef(Z).

◆□▶ ◆□▶ ◆□▶ ◆□▶ □ のQで

Lemma

Lemma 3. (Contraction theorem,Ledoux and Talagrand,1991) Let $z_1, ..., z_n$ be nonrandom elements of some space \mathcal{Z} and let \mathcal{F} be a class of real valued functions on \mathcal{Z} . Let $\varepsilon_1, ..., \varepsilon_n$ be a Rademacher sequence. Consider Lipschitz functions $\gamma_i : \mathbf{R} \mapsto \mathbf{R}$, that is,

$$|\gamma_i(\mathbf{s}) - \gamma_i(\tilde{\mathbf{s}})| \leq |\mathbf{s} - \tilde{\mathbf{s}}|, \forall \mathbf{s}, \tilde{\mathbf{s}} \in \mathbf{R}.$$

Then for any function $\tilde{f} : \mathcal{Z} \mapsto \mathbf{R}$, we have

$$E\{\sup_{f\in\mathcal{F}}|\mathbb{P}_{n}\varepsilon(\gamma(f)-\gamma(\tilde{f}))|\}\leq 2E\{\sup_{f\in\mathcal{F}}|\mathbb{P}_{n}\varepsilon(f-\tilde{f})|\}.$$

・ロット (雪) (日) (日) (日)

Lemma

Lemma 4. (Concentration theorem,Massart,2000) Let $Z_1, ..., Z_n$ be independent random variables with values in some space \mathcal{Z} and let $\gamma \in \Gamma$, a class of real valued functions on \mathcal{Z} . We assume that for some positive constants $I_{i,\gamma}$ and $u_{i,\gamma}$, $I_{i,\gamma} \leq \gamma(Z_i) \leq u_{i,\gamma} \forall \gamma \in \Gamma$. Define

$$L^2 = \sup_{\gamma \in \Gamma} \sum_{i=1}^n (u_{i,\gamma} - I_{i,\gamma})^2 / n, \boldsymbol{Z} = \sup_{\gamma \in \Gamma} |(\mathbb{P}_n - P)\gamma(\boldsymbol{Z})|,$$

then for any t > 0,

$$\mathcal{P}(\mathbf{Z} \geq E\mathbf{Z} + t) \leq \exp(-rac{nt^2}{2L^2}).$$

• Let
$$N > 0$$
, define $\mathcal{B}(N) = \{\beta \in \mathcal{B} : \|\beta - \beta_0\| \le N\}$, and

$$\mathbb{G}_1(N) = \sup_{\beta \in \mathcal{B}(N)} |(\mathbb{P}_n - P)\{I(\boldsymbol{X}^T\beta, Y) - I(\boldsymbol{X}^T\beta_0, Y)\}I_n(\boldsymbol{X}, Y)|.$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

Lemma

Lemma 5. For all t > 0, it holds that

 $P(\mathbb{G}_1(N) \ge 4Nk_n(q/n)^{1/2}(1+t)) \le \exp(-2t^2/K_n^2).$

- Proof of Lemma 5:
- On the set Ω_n ,

$$\begin{aligned} |I(\boldsymbol{X}^{T}\boldsymbol{\beta},\mathbf{Y}) - I(\boldsymbol{X}^{T}\boldsymbol{\beta}_{0},\mathbf{Y})| &\leq k_{n}|\boldsymbol{X}^{T}(\boldsymbol{\beta}-\boldsymbol{\beta}_{0})| \\ &\leq k_{n}\|\boldsymbol{X}\|\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\| \\ &\leq k_{n}\cdot\boldsymbol{q}^{1/2}K_{n}\cdot N, \end{aligned}$$

by Lipschitz and Cauchy-Schwartz respectively. Hence, $L^2 = 4k_n^2 q K_n^2 N^2$.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

• On the other hand,

٩

$$\begin{split} E\mathbb{G}_{1}(N) &\leq 2E[\sup_{\beta\in\mathcal{B}(N)}|\mathbb{P}_{n}\varepsilon\{I(\boldsymbol{X}^{T}\beta,\boldsymbol{Y})-I(\boldsymbol{X}^{T}\beta_{0},\boldsymbol{Y})\}I_{n}(\boldsymbol{X},\boldsymbol{Y})|]\\ &\leq 4k_{n}E[\sup_{\beta\in\mathcal{B}(N)}|\mathbb{P}_{n}\varepsilon\boldsymbol{X}^{T}(\beta-\beta_{0})I_{n}(\boldsymbol{X},\boldsymbol{Y})|]\\ &\leq 4k_{n}E||\mathbb{P}_{n}\varepsilon\boldsymbol{X}I_{n}(\boldsymbol{X},\boldsymbol{Y})||\sup_{\beta\in\mathcal{B}(N)}||\beta-\beta_{0}||\\ &\leq 4k_{n}N(E||\mathbb{P}_{n}\varepsilon\boldsymbol{X}I_{n}(\boldsymbol{X},\boldsymbol{Y})||^{2})^{1/2}\\ &= 4k_{n}N(E||\boldsymbol{X}||^{2}I_{n}(\boldsymbol{X},\boldsymbol{Y})/n)^{1/2}\\ &\leq 4k_{n}N(E||\boldsymbol{X}||^{2}/n)^{1/2} = 4k_{n}N(q/n)^{1/2}. \end{split}$$

• Then, use lemma 4,

$$P(\mathbb{G}_1(N) \ge 4Nk_n(q/n)^{1/2}(1+t)) \le \exp{-2t^2/K_n^2}.$$

• Proof of Theorem 1. (See Appendix)

Outline

Introduction

- 2 Generalized Linear Models(GLMs or GLIM)
- Independence Screening with MMLE

- Controlling False Selection Rates
- 6 A Likelihood Ratio Screening
- 7 Numerical Results
 - 8 Conclusion Remarks

- First, for the sure screening purpose, if a variable X_j is jointly important (β_j^{*} ≠ 0), will it still be marginally important (β_j^M ≠ 0)?
- Second, for the model selection consistency purpose, if a variable X_j is jointly unimportant (β_j^{*} = 0), will it still be marginally unimportant (β_j^M = 0)?

(日) (日) (日) (日) (日) (日) (日) (日)

Theorem

Theorem 2. For $j = 1, ..., p_n$, the marginal regression parameters $\beta_i^M = 0$ iff $cov(b'(\mathbf{X}^T \beta^*), X_j) = 0$.

Corollary

Corollary 1. If the partial orthogonality condition holds, i.e., $\{X_j, j \notin \mathcal{M}_{\star}\}$ is independent of $\{X_i, i \in \mathcal{M}_{\star}\}$, then $\beta_j^M = 0$, for $j \notin \mathcal{M}_{\star}$.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

• Proof of Theorem 2. (See Appendix)

Theorem

Theorem 3. If $|cov(b'(\mathbf{X}^T \beta^*), X_j)| \ge c_1 n^{-\kappa}$ for $j \in \mathcal{M}_*$ and a positive constant $c_1 > 0$, then there exists a positive constant c_2 such that $\min_{j \in \mathcal{M}_*} |\beta_j^M| \ge c_2 n^{-\kappa}$, provided that b''(.) is bounded or

 $EG(a|X_j|)|X_j|I(|X_j| \ge n^{\eta}) \le dn^{-\kappa}$, for some $0 < \eta < \kappa$,

and some sufficiently small positive constants a and d, where $G(|x|) = \sup_{|u| \le |x|} |b'(u)|$.

(日) (日) (日) (日) (日) (日) (日) (日)

• Proof of Theorem 3. (See Appendix)

- Note that for the normal and Bernoulli distributions, b''(.) is bounded, whereas for the Poisson distribution, $G(|x|) = \exp(|x|)$ and Theorem 3 requires the tails of X_j to be light.
- In the proof of Theorem 5, it can be shown that

$$\sum_{j=1}^{p_n} |\beta_j^M|^2 = O(\|\Sigma\beta^\star\|^2) = O(\lambda_{\max}(\Sigma)),$$

which means there can not be too many variables that have marginal coefficient $|\beta_j^M|$ that exceeds certain thresholding level. That achieves the sparsity in final selected model.

Gaussian Covariates

• Proposition 1. Suppose that Z and X are jointly normal with mean zero and standard deviation 1. For a strictly monotonic function f, cov(X, Z) = 0 iff cov(X, f(Z)) = 0, provided the latter covariance exists. In addition,

$$|cov(X, f(Z))| \ge |
ho| \inf_{|x| \le c|
ho|} |g'(x)| EX^2 I(|X| \le c),$$

for any c > 0, where $\rho = EXZ$, $g(x) = Ef(x + \varepsilon)$ with $\varepsilon \sim N(0, 1 - \rho^2)$.

Using Proposition 1, for Gaussian covariates, β_j^M = 0 iff cov(X^Tβ^{*}, X_j) = 0. Also, condition for Theorem 3 is that |cov(X^Tβ^{*}, X_j)| ≥ c₁n^{-κ}, which is a minimum condition required even for the least squares model (Fan and Lv, 2008).

Regularity Conditions

- A'. The marginal Fisher information:
 I_j(β_j) = E{b''(X_j^Tβ_j)X_jX_j^T} is finite and positive definite at
 β_j = β_j^M, for j = 1, ..., p_n. Moreover, ||*I_j(β_j)*||_B is bounded from above.
- B'. The second derivative of b(θ) is continuous and positive. There exists an ε₁ > 0 such that for all j = 1,..., p_n,

$$\sup_{\boldsymbol{\beta}\in\mathcal{B}, \|\boldsymbol{\beta}-\boldsymbol{\beta}_{j}^{M}\|\leq\varepsilon_{1}}|\boldsymbol{Eb}(\boldsymbol{X}_{j}^{T}\boldsymbol{\beta})\boldsymbol{I}(|\boldsymbol{X}_{j}|>\boldsymbol{K}_{n})|\leq o(n^{-1}).$$

 C'. For all β_j ∈ B, we have
 E[I(X^T_jβ_j, Y) − I(X^T_jβ^M_j, Y)] ≥ V||β_j − β^M_j||², for some
 positive V, bounded from below uniformly over j = 1, ..., p_n.
 D. There exists some positive constants m₀, m₁, s₀, s₁ and α, such that for sufficiently large t,

$$P(|X_j| > t) \le (m_1 - s_1) \exp\{-m_0 t^{\alpha}\}, j = 1, ..., p_n,$$

and that

$$\begin{split} & E\exp(b(\boldsymbol{X}^{T}\boldsymbol{\beta}^{\star}+\boldsymbol{s}_{0})-b(\boldsymbol{X}^{T}\boldsymbol{\beta}^{\star}))\\ & +E\exp(b(\boldsymbol{X}^{T}\boldsymbol{\beta}^{\star}-\boldsymbol{s}_{0})-b(\boldsymbol{X}^{T}\boldsymbol{\beta}^{\star}))\leq \boldsymbol{s}_{1}. \end{split}$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

• E. The conditions in Theorem 3 hold.

 Conditions A'-C' are satisfied in a lot of examples of GLMs, such as linear regression, logistic regression and Poisson regression. Note that the second part of condition D ensures the tail of the response variable Y to be exponentially light, as shown in the following.

Lemma

Lemma 1. If condition D holds, for any t > 0,

 $P(|\mathbf{Y}| \geq m_0 t^{\alpha}/s_0) \leq s_1 \exp(-m_0 t^{\alpha}).$

(日) (日) (日) (日) (日) (日) (日) (日)

Proof of Lemma 1

• Proof of Lemma 1. (See Appendix)

Theorem 4

Theorem

Theorem 4. Suppose that conditions A', B', C' and D hold. (1) If $n^{1-2\kappa}/(k_n^2 K_n^2) \to \infty$, then for any $c_3 > 0$, there exists a positive constant c_4 such that

$$\begin{split} & P(\max_{1\leq j\leq p_n}|\hat{\beta}_j^M-\beta_j^M|\geq c_3n^{-\kappa})\\ \leq & p_n\{\exp(-c_4n^{1-2\kappa}/(k_n^2K_n^2))+nm_1\exp(-m_0K_n^\alpha)\}. \end{split}$$

(2) If, in addition, condition E holds, then by taking $\gamma_n = c_5 n^{-\kappa}$ with $c_5 \le c_2/2$, we have

$$P(\mathcal{M}_{\star} \subset \hat{\mathcal{M}}_{\gamma_n}) \\ \geq 1 - s_n \{ \exp(-c_4 n^{1-2\kappa}/(k_n^2 K_n^2)) + nm_1 \exp(-m_0 K_n^{\alpha}) \}.$$

Proof of Theorem 4

• Proof of Theorem 4. (See Appendix)

- No conditions on covariance matrix!
- If we assume that min_{j∈M*} |cov(b'(**X**^Tβ*), X_j)| ≥ c₁n^{-κ+δ} for any δ > 0, then one can take γ_n = cn^{-κ+δ/2} for any c > 0 in Theorem 4. This is essentially the thresholding used in Fan and Lv (2008).

(日) (日) (日) (日) (日) (日) (日) (日)

- F. The variance var(X^Tβ^{*}) is bounded from above and below.
- G. Either b''(.) is bounded or $\mathbf{X}_M = (X_1, ..., X_{p_n})^T$ follows an elliptically contoured distribution, i.e., $\mathbf{X}_M = \Sigma_1^{1/2} R U$, and $|Eb'(\mathbf{X}^T \beta^*)(\mathbf{X}^T \beta^* \beta_0^*)|$ is bounded, where U is uniformly distributed on the unit sphere in *p*-dimensional Euclidean space, independent of the nonnegative random variable R, and $\Sigma_1 = var(\mathbf{X}_M)$.

Theorem

Theorem 5. Under conditions A', B', C', D, F and G, we have for any $\gamma_n = c_5 n^{-\kappa}$, there exists a c_4 such that

$$\begin{split} & \mathcal{P}[|\hat{\mathcal{M}}_{\gamma_n}| \leq O\{n^{2\kappa}\lambda_{\max}(\Sigma)\}] \\ \geq & 1 - p_n\{\exp(-c_4n^{1-2\kappa}/(k_n^2K_n^2)) + nm_1\exp(-m_0K_n^\alpha)\}. \end{split}$$

Proof of Theorem 5

• Proof of Theorem 5. (See Appendix)

Outline

1 Introduction

- 2 Generalized Linear Models(GLMs or GLIM)
- 3 Independence Screening with MMLE
- An Exponential Bound for QMLE (a more general result)
- 5 Sure Screening Properties with MMLE
 - Population Aspects
 - Sampling Aspects: uniform convergence and sure screening

- Controlling False Selection Rates
- 6 A Likelihood Ratio Screening
 - Numerical Results
 - Conclusion Remarks

- The likelihood ratio screening is equivalent to the MMLE screening in the sense that they both possess the sure screening property and that the number of selected variables of the two methods are of the same order of magnitude.
- Marginal utility: letting $\hat{L}_0 = \min_{\beta_0} \mathbb{P}_n I(\mathbf{Y}, \beta_0)$, define $\hat{L}_j = \hat{L}_0 \min_{\beta_0, \beta_j} \mathbb{P}_n I(\mathbf{Y}_i, \beta_0 + X_j \beta_j)$.
- Feature ranking: select features with largest marginal utilities: Â_{νn} = {1 ≤ j ≤ p_n : L_j ≥ ν_n}.
- The main results are Theorems 6-9, which are analogous to Theorem 2-5.

Outline

1 Introduction

- 2 Generalized Linear Models(GLMs or GLIM)
- 3 Independence Screening with MMLE
- An Exponential Bound for QMLE (a more general result)
- 5 Sure Screening Properties with MMLE
 - Population Aspects
 - Sampling Aspects: uniform convergence and sure screening

- Controlling False Selection Rates
- 6 A Likelihood Ratio Screening

Numerical Results

Conclusion Remarks

- Consider 3 settings of how to generate the covariates in logistic regressions and linear models
- Compare two SIS procedures with LASSO, and SCAD
- The minimum model size is used as a measure of the effectiveness of a screening method
- The initial intension is to demonstrate that the simple SIS does not perform much worse than the far more complicated procedures like the LASSO and the SCAD
- The SIS can even outperform those more complicated methods in terms of variable screening

Outline

1 Introduction

- 2 Generalized Linear Models(GLMs or GLIM)
- 3 Independence Screening with MMLE
- An Exponential Bound for QMLE (a more general result)
- 5 Sure Screening Properties with MMLE
 - Population Aspects
 - Sampling Aspects: uniform convergence and sure screening
 - Controlling False Selection Rates
- 6 A Likelihood Ratio Screening
- 7 Numerical Results

- Any surrogates screening, as long as which can preserve the non-sparsity structure of the true model and is feasible in computation, can be a good option for population variable screening.
- The proposed procedure does not cover all GLMs, such as some non-canonical link cases.
- The main idea of the technical proofs is broadly applicable.
- Another important extension is to generalize the concept of marginal regression to the marginal group regression, where the number of covariates *m* in each marginal regression is greater than or equal to one. This leads to a new procedure called group variables screening.

• How to choose the tuning parameter γ_n is another interesting and important problem.

THANK YOU!!
