

NSF StatGen 2009
Bayesian Interval Mapping
Brian S. Yandell, UW-Madison
www.stat.wisc.edu/~yandell/statgen

- overview: multiple QTL approaches
- Bayesian QTL mapping & model selection
- data examples in detail
- software demos: R/qtl and R/qtlbim

Real knowledge is to know the extent of one's ignorance.
Confucius (on a bench in Seattle)

1. what is the goal of QTL study?

- uncover underlying biochemistry
 - identify how networks function, break down
 - find useful candidates for (medical) intervention
 - epistasis may play key role
 - statistical goal: maximize number of correctly identified QTL
- basic science/evolution
 - how is the genome organized?
 - identify units of natural selection
 - additive effects may be most important (Wright/Fisher debate)
 - statistical goal: maximize number of correctly identified QTL
- select “elite” individuals
 - predict phenotype (breeding value) using suite of characteristics (phenotypes) translated into a few QTL
 - statistical goal: minimize prediction error

cross two inbred lines

→ linkage disequilibrium

→ associations

→ linked segregating QTL

(after Gary Churchill)

NSF StatGen: Yandell © 2009

3

problems of single QTL approach

- wrong model: biased view
 - fool yourself: bad guess at locations, effects
 - detect ghost QTL between linked loci
 - miss epistasis completely
- low power
- bad science
 - use best tools for the job
 - maximize scarce research resources
 - leverage already big investment in experiment

NSF StatGen: Yandell © 2009

4

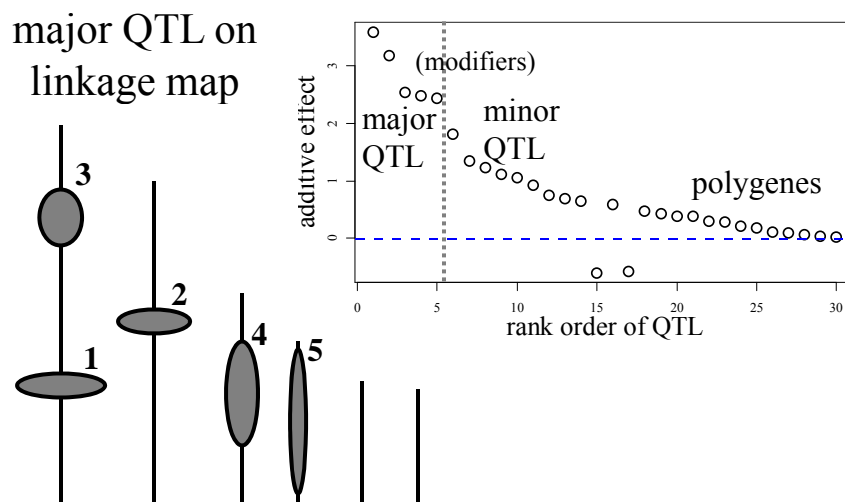

advantages of multiple QTL approach

- improve statistical power, precision
 - increase number of QTL detected
 - better estimates of loci: less bias, smaller intervals
- improve inference of complex genetic architecture
 - patterns and individual elements of epistasis
 - appropriate estimates of means, variances, covariances
 - asymptotically unbiased, efficient
 - assess relative contributions of different QTL
- improve estimates of genotypic values
 - less bias (more accurate) and smaller variance (more precise)
 - mean squared error = $MSE = (\text{bias})^2 + \text{variance}$

NSF StatGen: Yandell © 2009

5

Pareto diagram of QTL effects

NSF StatGen: Yandell © 2009

6

limits of multiple QTL?

- limits of statistical inference
 - power depends on sample size, heritability, environmental variation
 - “best” model balances fit to data and complexity (model size)
 - genetic linkage = correlated estimates of gene effects
- limits of biological utility
 - sampling: only see some patterns with many QTL
 - marker assisted selection (Bernardo 2001 *Crop Sci*)
 - 10 QTL ok, 50 QTL are too many
 - phenotype better predictor than genotype when too many QTL
 - increasing sample size may not give multiple QTL any advantage
 - hard to select many QTL simultaneously
 - 3^m possible genotypes to choose from

NSF StatGen: Yandell © 2009

7

QTL below detection level?

- problem of selection bias
 - QTL of modest effect only detected sometimes
 - effects overestimated when detected
 - repeat studies may fail to detect these QTL
- think of probability of detecting QTL
 - avoids sharp in/out dichotomy
 - avoid pitfalls of one “best” model
 - examine “better” models with more probable QTL
- rethink formal approach for QTL
 - directly allow uncertainty in genetic architecture
 - QTL model selection over genetic architecture

NSF StatGen: Yandell © 2009

8

3. Bayesian vs. classical QTL study

- classical study
 - *maximize* over unknown effects
 - *test* for detection of QTL at loci
 - model selection in stepwise fashion
- Bayesian study
 - *average* over unknown effects
 - *estimate* chance of detecting QTL
 - sample all possible models
- both approaches
 - average over missing QTL genotypes
 - scan over possible loci

Bayesian idea

- Reverend Thomas Bayes (1702-1761)
 - part-time mathematician
 - buried in Bunhill Cemetary, Moongate, London
 - famous paper in 1763 *Phil Trans Roy Soc London*
 - was Bayes the first with this idea? (Laplace?)
- basic idea (from Bayes' original example)
 - two billiard balls tossed at random (uniform) on table
 - where is first ball if the second is to its left?
 - prior: anywhere on the table
 - posterior: more likely toward right end of table

QTL model selection: key players

- observed measurements
 - y = phenotypic trait
 - m = markers & linkage map
 - i = individual index ($1, \dots, n$)
- missing data
 - missing marker data
 - q = QT genotypes
 - alleles QQ, Qq, or qq at locus
- unknown quantities
 - λ = QT locus (or loci)
 - μ = phenotype model parameters
 - γ = QTL model/genetic architecture
- $\text{pr}(q|m, \lambda, \gamma)$ genotype model
 - grounded by linkage map, experimental cross
 - recombination yields multinomial for q given m
- $\text{pr}(y|q, \mu, \gamma)$ phenotype model
 - distribution shape (assumed normal here)
 - unknown parameters μ (could be non-parametric)

NSF StatGen: Yandell © 2009

11

Bayes posterior vs. maximum likelihood

- **LOD: classical Log ODDs**
 - maximize likelihood over effects μ
 - R/qt1 scanone/scantwo: method = "em"
- **LPD: Bayesian Log Posterior Density**
 - average posterior over effects μ
 - R/qt1 scanone/scantwo: method = "imp"

$$\text{LOD}(\lambda) = \log_{10} \{ \max_{\mu} \text{pr}(y | m, \mu, \lambda) \} + c$$

$$\text{LPD}(\lambda) = \log_{10} \{ \text{pr}(\lambda | m) \int \text{pr}(y | m, \mu, \lambda) \text{pr}(\mu) d\mu \} + C$$

likelihood mixes over missing QTL genotypes:

$$\text{pr}(y | m, \mu, \lambda) = \sum_q \text{pr}(y | q, \mu) \text{pr}(q | m, \lambda)$$

NSF StatGen: Yandell © 2009

12

LOD & LPD: 1 QTL

n.ind = 100, 1 cM marker spacing

NSF StatGen: Yandell © 2009

13

LOD & LPD: 1 QTL

n.ind = 100, 10 cM marker spacing

NSF StatGen: Yandell © 2009

14

marginal LOD or LPD

- compare two genetic architectures (γ_2, γ_1) at each locus
 - with (γ_2) or without (γ_1) another QTL at locus λ
 - preserve model hierarchy (e.g. drop any epistasis with QTL at λ)
 - with (γ_2) or without (γ_1) epistasis with QTL at locus λ
 - γ_2 contains γ_1 as a sub-architecture
- allow for multiple QTL besides locus being scanned
 - architectures γ_1 and γ_2 may have QTL at several other loci
 - use marginal LOD, LPD or other diagnostic
 - posterior, Bayes factor, heritability

$$\text{LOD}(\lambda | \gamma_2) - \text{LOD}(\lambda | \gamma_1)$$

$$\text{LPD}(\lambda | \gamma_2) - \text{LPD}(\lambda | \gamma_1)$$

NSF StatGen: Yandell © 2009

15

LPD: 1 QTL vs. multi-QTL marginal contribution to LPD from QTL at λ

NSF StatGen: Yandell © 2009

16

substitution effect: 1 QTL vs. multi-QTL single QTL effect vs. marginal effect from QTL at λ

NSF StatGen: Yandell © 2009

17

why use a Bayesian approach?

- first, do *both* classical and Bayesian
 - always nice to have a separate validation
 - each approach has its strengths and weaknesses
- classical approach works quite well
 - selects large effect QTL easily
 - directly builds on regression ideas for model selection
- Bayesian approach is comprehensive
 - samples most probable genetic architectures
 - formalizes model selection within one framework
 - readily (!) extends to more complicated problems

NSF StatGen: Yandell © 2009

18

1. Bayesian strategy for QTL study

- augment data (y, m) with missing genotypes q
- study unknowns (μ, λ, γ) given augmented data (y, m, q)
 - find better genetic architectures γ
 - find most likely genomic regions = QTL = λ
 - estimate phenotype parameters = genotype means = μ
- sample from posterior in some clever way
 - multiple imputation (Sen Churchill 2002)
 - Markov chain Monte Carlo (MCMC)
 - (Satagopan et al. 1996; Yi et al. 2005, 2007)

$$\text{posterior} = \frac{\text{likelihood} * \text{prior}}{\text{constant}}$$

$$\text{posterior for } q, \mu, \lambda, \gamma = \frac{\text{phenotype likelihood} * [\text{prior for } q, \mu, \lambda, \gamma]}{\text{constant}}$$

$$\text{pr}(q, \mu, \lambda, \gamma | y, m) = \frac{\text{pr}(y | q, \mu, \gamma) * [\text{pr}(q | m, \lambda, \gamma) \text{pr}(\mu | \gamma) \text{pr}(\lambda | m, \gamma) \text{pr}(\gamma)]}{\text{pr}(y | m)}$$

NSF StatGen: Yandell © 2009

19

what values are the genotypic means?
phenotype model $\text{pr}(y|q, \mu)$

NSF StatGen: Yandell © 2009

20

Bayes posterior QTL means

posterior centered on sample genotypic mean
but shrunken slightly toward overall mean

$$\text{phenotype mean: } E(y | q) = \mu_q \quad V(y | q) = \sigma^2$$

$$\text{genotypic prior: } E(\mu_q) = \bar{y}_\bullet \quad V(\mu_q) = \kappa \sigma^2$$

$$\text{posterior: } E(\mu_q | y) = b_q \bar{y}_q + (1 - b_q) \bar{y}_\bullet \quad V(\mu_q | y) = b_q \sigma^2 / n_q$$

$$n_q = \text{count}\{q_i = q\} \quad \bar{y}_q = \frac{\text{sum}_{\{q_i=q\}} y_i}{n_q}$$

$$\text{shrinkage: } b_q = \frac{\kappa n_q}{\kappa n_q + 1} \rightarrow 1$$

NSF StatGen: Yandell © 2009

21

partition genotypic effects on phenotype

- phenotype depends on genotype
- genotypic value partitioned into
 - main effects of single QTL
 - epistasis (interaction) between pairs of QTL

$$\begin{aligned} \mu_q &= \beta_0 + \beta_q = E(Y; q) \\ \beta_q &= \beta(q_2) + \beta(q_2) + \beta(q_1, q_2) \end{aligned}$$

NSF StatGen: Yandell © 2009

22

$\text{pr}(q/m, \lambda)$ recombination model

$$\text{pr}(q/m, \lambda) = \text{pr}(\text{geno} \mid \text{map}, \text{locus}) \approx \text{pr}(\text{geno} \mid \text{flanking markers}, \text{locus})$$

NSF StatGen: Yandell © 2009

23

multiple imputations of genotypes

what are likely QTL genotypes q ?
 how does phenotype y improve guess?

NSF StatGen: Yandell © 2009

25

posterior on QTL genotypes q

- full conditional of q given data, parameters
 - proportional to prior $\text{pr}(q | m, \lambda)$
 - weight toward q that agrees with flanking markers
 - proportional to likelihood $\text{pr}(y | q, \mu)$
 - weight toward q with similar phenotype values
 - posterior recombination model balances these two
- this *is* the E-step of EM computations

$$\text{pr}(q | y, m, \mu, \lambda) = \frac{\text{pr}(y | q, \mu) * \text{pr}(q | m, \lambda)}{\text{pr}(y | m, \mu, \lambda)}$$

NSF StatGen: Yandell © 2009

26

what is the genetic architecture γ ?

- which positions correspond to QTLs?
 - priors on loci (previous slide)
- which QTL have main effects?
 - priors for presence/absence of main effects
 - same prior for all QTL
 - can put prior on each d.f. (1 for BC, 2 for F2)
- which pairs of QTL have epistatic interactions?
 - prior for presence/absence of epistatic pairs
 - depends on whether 0,1,2 QTL have main effects
 - epistatic effects less probable than main effects

NSF StatGen: Yandell © 2009

27

γ = genetic architecture:

loci:

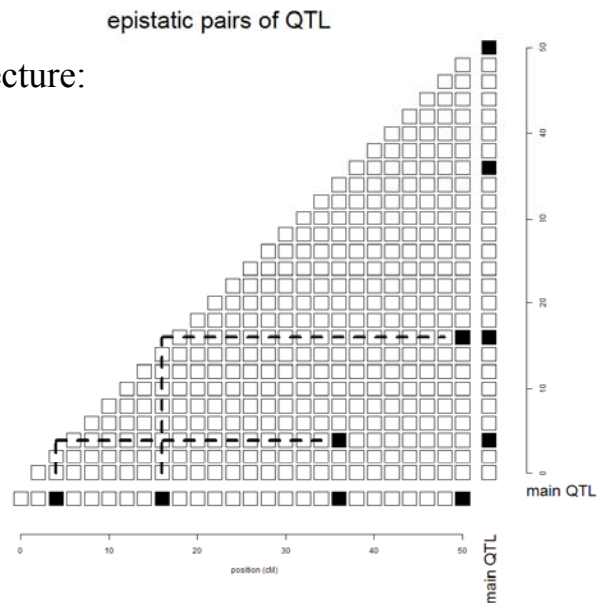

main QTL

epistatic pairs

effects:

add, dom

aa, ad, dd

NSF StatGen: Yandell © 2009

28

Bayesian priors & posteriors

- augmenting with missing genotypes q
 - prior is recombination model
 - posterior is (formally) E step of EM algorithm
- sampling phenotype model parameters μ
 - prior is “flat” normal at grand mean (no information)
 - posterior shrinks genotypic means toward grand mean
 - (details for unexplained variance omitted here)
- sampling QTL genetic architecture model γ
 - number of QTL
 - prior is Poisson with mean from previous IM study
 - locations of QTL loci λ
 - prior is flat across genome (all loci equally likely)
 - genetic architecture of main effects and epistatic interactions
 - priors on epistasis depend on presence/absence of main effects

NSF StatGen: Yandell © 2009

29

2. Markov chain sampling

- construct Markov chain around posterior
 - want posterior as stable distribution of Markov chain
 - in practice, the chain tends toward stable distribution
 - initial values may have low posterior probability
 - burn-in period to get chain mixing well
- sample QTL model components from full conditionals
 - sample locus λ given q, γ (using Metropolis-Hastings step)
 - sample genotypes q given λ, μ, γ (using Gibbs sampler)
 - sample effects μ given q, γ (using Gibbs sampler)
 - sample QTL model γ given λ, μ, q (using Gibbs or M-H)

$$(\lambda, q, \mu, \gamma) \sim \text{pr}(\lambda, q, \mu, \gamma | y, m)$$

$$(\lambda, q, \mu, \gamma)_1 \rightarrow (\lambda, q, \mu, \gamma)_2 \rightarrow \cdots \rightarrow (\lambda, q, \mu, \gamma)_N$$

NSF StatGen: Yandell © 2009

30

MCMC sampling of unknowns (μ, q, λ) for given genetic architecture γ

$$\begin{array}{l} \mu \sim \frac{\text{pr}(y | q, \mu)\text{pr}(\mu)}{\text{pr}(y | q)} \\ \downarrow \\ q \sim \text{pr}(q | y, m, \mu, \lambda) \\ \downarrow \\ \lambda \sim \frac{\text{pr}(q | m, \lambda)\text{pr}(\lambda | m)}{\text{pr}(q | m)} \end{array}$$

NSF StatGen: Yandell © 2009

31

Gibbs sampler for two genotypic means

- want to study two correlated effects β_1, β_2
 - assume correlation ρ is known
- sample from full distribution?
- or use Gibbs sampler:
 - sample each effect from its full conditional given the other
 - pick order of sampling at random
 - repeat many times

$$\begin{pmatrix} \beta_1 \\ \beta_2 \end{pmatrix} \sim N\left(\begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 1 & \rho \\ \rho & 1 \end{pmatrix}\right)$$

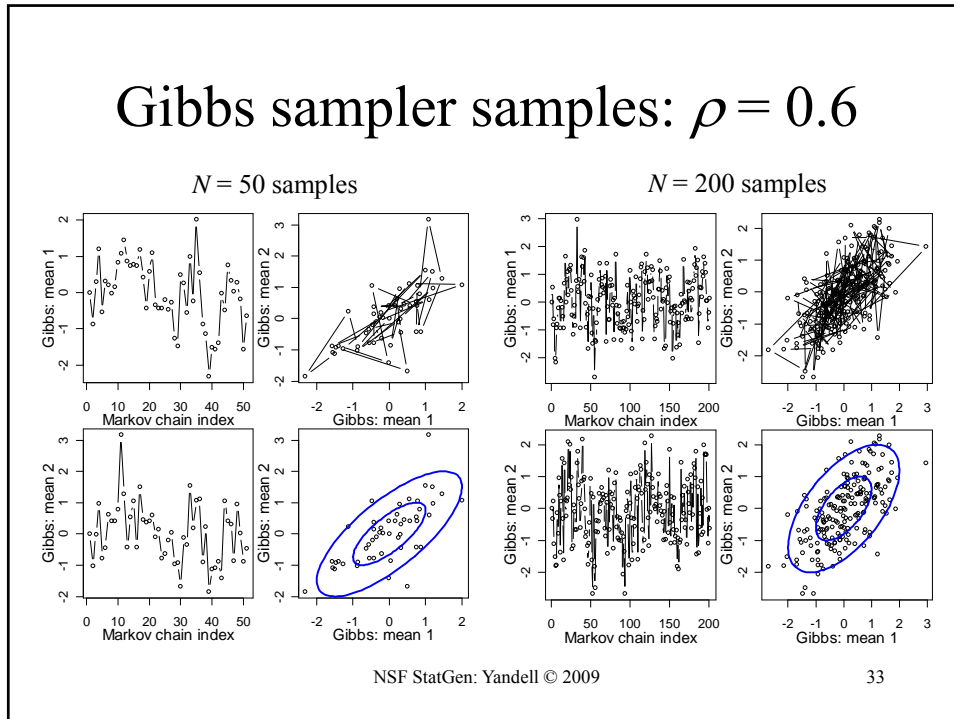

$$\beta_1 \sim N(\rho\beta_2, 1 - \rho^2)$$

$$\beta_2 \sim N(\rho\beta_1, 1 - \rho^2)$$

NSF StatGen: Yandell © 2009

32

Gibbs sampler samples: $\rho = 0.6$

Gibbs sampler for loci indicators

- QTL at pseudomarkers
- loci indicators γ
 - $\gamma = 1$ if QTL present
 - $\gamma = 0$ if no QTL present
- Gibbs sampler on loci indicators γ
 - relatively easy to incorporate epistasis
 - Yi *et al.* (2005 *Genetics*)
 - (earlier work of Yi, Ina Hoeschele)

$$\mu_q = \mu + \gamma_1 \beta(q_1) + \gamma_2 \beta(q_2), \quad \gamma_k = 0, 1$$

49

what is best estimate of QTL?

- find most probable pattern
 - 1,4,6,15,6:15 has posterior of 3.4%
- estimate locus across all nested patterns
 - Exact pattern seen ~100/3000 samples
 - Nested pattern seen ~2000/3000 samples
- estimate 95% confidence interval using quantiles

```
> best <- qb.best(qbHyper)
> summary(best)$best
```

	chrom	locus	locus.LCL	locus.UCL	n.qtl	
	247	1	69.9	24.44875	95.7985	0.8026667

50

what patterns are “near” the best?

- size & shade ~ posterior
- distance between patterns
 - sum of squared attenuation
 - match loci between patterns
 - squared attenuation = $(1-2r)^2$
 - sq.atten in scale of LOD & LPD
- multidimensional scaling
 - MDS projects distance onto 2-D
 - think mileage between cities
