Numerical Differentiation

• Derivatives can be approximated using Newton's formula,

$$\frac{df}{dx}\approx\frac{f\left(x+h\right)-f\left(x\right)}{h},$$

for some small h close to 0.

• The derivative of f at x is usually approximated by,

$$\frac{df}{dx} \approx \frac{f(x+h) - f(x-h)}{2h}.$$

Differentiation 00000000

Integration 0000000000

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Finite Differences

• There are more accurate approximations using finite differences, for example, $\frac{df}{dx} \approx \frac{-f(x+2h) + 8f(x+h) - 8f(x-h) + f(x-2h)}{12h},$

for some small h close to 0.

Partial Derivatives

• Partial derivatives of a multivariate function are derivatives with respect to one of the variables holding the other variables constant.

$$\frac{\partial f(x,y)}{\partial x} \approx \frac{f(x+h,y) - f(x-h,y)}{2h}.$$
$$\frac{\partial f(x,y)}{\partial y} \approx \frac{f(x,y+h) - f(x,y-h)}{2h}.$$

Differentiation

Integration 00000000000

Partial Derivatives Too Math

• Higher order derivatives can be approximated in a similar way,

$$\frac{\partial^2 f\left(x,y\right)}{\partial x^2} \approx \frac{f\left(x+h,y\right) - 2f\left(x,y\right) + f\left(x-h,y\right)}{h^2},\\ \frac{\partial^2 f\left(x,y\right)}{\partial y^2} \approx \frac{f\left(x,y+h\right) - 2f\left(x,y\right) + f\left(x,y-h\right)}{h^2}.$$

and,

$$\frac{\partial f(x,y)}{\partial x \partial y} \approx \frac{f(x+h,y+h) + f(x-h,y-h)}{4h^2} - \frac{f(x+h,y-h) + f(x-h,y+h)}{4h^2}.$$

Gradient Math

• The gradient of a multivariate function is the vector of (partial) derivatives, one for each variable.

$$\nabla f(x,y) = \begin{bmatrix} \frac{\partial f}{\partial x} \\ \frac{\partial f}{\partial y} \end{bmatrix}.$$

Derivative as a Function

- It is possible to compute the numerical derivative as a function (a MATLAB function, not a closed form expression of the function).
- function d = df(f)
- **2** h = 0.0001;
- end

Differentiation

Integration 0000000000

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Automatic Differentiation

- diff (y) computes the difference between consecutive elements of y and returns (y₂ y₁, y₃ y₂, ..., y_n y_{n-1}) and can be used to approximate the derivative of the discretized function y = f (x).
- *diff (f)* computes the derivative of *f* and returns a function. It requires MATLAB's Symbolic Math Toolbox.

Numerical Integration or Quadrature

- Definite integrals can be approximated using finite Riemann sums.
- If the right Riemann sum is used, then,

$$\int_{x_0}^{x_1} f(x) dx \approx \sum_{i=1}^n f(x_0 + i \cdot h) h,$$

for $h = \frac{x_1 - x_0}{n}$, for some large *n*. • If the left Riemann sum is used, then, $\int_{-\infty}^{x_1} c(x) dx = \sum_{n=1}^{n} c(x_n - x_n) dx$

$$\int_{x_0}^{1} f(x) \, dx \approx \sum_{i=1}^{n} f(x_0 + (i-1) \cdot h) \, h,$$

for $h = \frac{x_1 - x_0}{n}$, for some large *n*.

Numerical Integration Diagram

Differentiation 0000000000 Integration 0000000000

Midpoint Rule

$$\int_{x_0}^{x_1} f(x) \, dx \approx \sum_{i=1}^n f(x_0 + (i - 0.5) \cdot h) \, h,$$

for $h = \frac{x_1 - x_0}{n}$, for some large *n*.

• If the trapezoidal rule is used, then,

$$\int_{x_0}^{x_1} f(x) \, dx \approx \sum_{i=1}^n \frac{1}{2} \left(f(x_0 + i \cdot h) + f(x_0 + (i-1) \cdot h) \right) h,$$

for
$$h = \frac{x_1 - x_0}{n}$$
, for some large *n*.

Adaptive and Monte Carlo Math

- The points at which the function is evaluated can be chosen adaptively or randomly.
- For example, smaller *h* can be used when f'(x) is large and larger *h* can be used when f'(x) is small.

Differentiation 0000000000 Integration 0000000000

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Double Integral Math

• Finite Riemann sums can be used to approximate multiple integrals too.

$$\int_{x_0}^{x_1} \int_{y_0}^{y_1} f(x, y) \, dx \, dy$$

$$\approx \sum_{i=1}^n \sum_{j=1}^m f(x_0 + (i - 0.5) \cdot h, y_0 + (j - 0.5) \cdot k) \cdot hk,$$

for
$$h = \frac{x_1 - x_0}{n}$$
, $k = \frac{y_1 - y_0}{m}$, for some large n, m .

• If $n \times m$ is too large, sometimes, Monte Carlo methods are used instead.

Indefinite Integral as a Function

- It is possible to compute the numerical integral as a function (a MATLAB function, not a closed form expression of the function). Instead of having the +C at the end, an arbitrary constant is used.
- function d = df(f)
- **2** h = 0.01;
- d = @(x)(sum(f(h:h:x)) * h);
- end
 - This approximation uses the right Riemann sum and it does not work on improper integrals.

Differentiation 0000000000 Integration 00000000000

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Integration Code

- integral (f, x0, x1) finds the numerical definite integral $\int_{x_0}^{x_1} f(x) dx.$
- *int* (*f*) finds the indefinite integral of *f* and returns a function.
 It requires MATLAB's Symbolic Math Toolbox.
