#### Game Tree Motivation

- The initial state is the beginning of the game.
- There are no goal states, but there are multiple terminal states in which the game ends.
- Each successor of a state represents a feasible action (or a move) in the game.
- The search problem is to find the terminal state with the lowest cost (or usually the highest reward).

Alpha Beta Pruning 000000 Heuristic 000000000

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

### Adversarial Search

- The main difference between finding solutions of games and standard search problems or local search problems is that part of the search is performed by an opponent adversarially.
- Usually, the opponent wants to maximize the cost or minimize the reward from the search. This type of search problems is called adversarial search.
- In game theory, the solution of a game is called an equilibrium. It is a path in which both players do not want to change actions.

Alpha Beta Pruning 000000 Heuristic 000000000

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

### Backward Induction

- Games are usually solved backward starting from the terminal states.
- Each player chooses the best action (successor) given the (already solved) optimal actions of all players in the subtrees (called subgames).

Alpha Beta Pruning 000000 Heuristic 000000000

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

## Zero-Sum Games

- If the sum of the reward or cost over all players at each terminal state is 0, the game is called a zero-sum game.
- Usually, for games with one winner: the reward for winning and the cost of losing are both 1. If the game ends with a tie, both players get 0.

## Nim Game Example

- Ten objects. Pick 1 or 2 each time. Pick the last one to win.
- A: Pick 1.
- B: Pick 2.
- C, D, E: Don't choose.

## Minimax Algorithm

• Use DFS on the game tree.

Alpha Beta Pruning 000000 Heuristic 000000000

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

### Minimax Algorithm

Algorithm

- Input: a game tree (V, E, c), and the current state s.
- Output: the value of the game at *s*.
- If s is a terminal state, return c(s).
- If the player is MAX, return the maximum value over all successors.

$$\alpha\left(\boldsymbol{s}\right) = \max_{\boldsymbol{s}' \in \boldsymbol{s}'\left(\boldsymbol{s}\right)} \beta\left(\boldsymbol{s}'\right)$$

• If the player is MIN, return the minimum value over all successors.

$$\beta\left(s\right) = \min_{s' \in s'(s)} \alpha\left(s'\right)$$

Alpha Beta Pruning 000000 Heuristic 000000000

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

#### Backtracking Discussion

• The optimal actions (solution paths) can be found by backtracking from all terminal states as in DFS.

$$\begin{aligned} s^{\star}\left(s\right) &= \arg\max_{s' \in s'(s)} \beta\left(s'\right) \text{ for MAX} \\ s^{\star}\left(s\right) &= \arg\min_{s' \in s'(s)} \alpha\left(s'\right) \text{ for MIN} \end{aligned}$$

Alpha Beta Pruning 000000 Heuristic 000000000

▲ロト ▲周ト ▲ヨト ▲ヨト ヨー のくで

## Minimax Performance

• The time and space complexity is the same as DFS. Note that D = d is the maximum depth of the terminal states.

$$T = 1 + b + b^2 + \dots + b^d$$
$$S = (b - 1) \cdot d$$

Alpha Beta Pruning 000000 Heuristic 000000000

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

## Non-deterministic Game

- For non-deterministic games in which chance can make a move (dice roll or coin flip), use expected reward or cost instead.
- The algorithm is also called expectiminimax.

Alpha Beta Pruning •00000 Heuristic 000000000

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

#### Pruning Motivation

- Time complexity is a problem because the computer usually has a limited amount of time to "think" and make a move.
- It is possible to reduce the time complexity by removing the branches that will not lead the current player to win. It is called the Alpha-Beta pruning.

Alpha Beta Pruning 000000 Heuristic 000000000

#### Alpha Beta Pruning Description

- $\bullet$  During DFS, keep track of both  $\alpha$  and  $\beta$  for each vertex.
- Prune the subtree with  $\alpha \ge \beta$ .

#### Alpha Beta Pruning Algorithm, Part II Algorithm

• If the player is MAX, return the maximum value over all successors.

$$\alpha (s) = \max_{s' \in s'(s)} \beta (s')$$
$$\beta (s) = \beta ( \text{ parent } (s))$$

- Stop and return  $\beta$  if  $\alpha \ge \beta$ .
- If the player is MIN, return the minimum value over all successors.

$$\beta(s) = \min_{s' \in s'(s)} \alpha(s')$$
$$\alpha(s) = \alpha(\text{ parent } (s))$$

• Stop and return  $\alpha$  if  $\alpha \ge \beta$ .

Alpha Beta Pruning

Heuristic 000000000

## Alpha Beta Performance

- In the best case, the best action of each player is the leftmost child.
- In the worst case, Alpha Beta is the same as minimax.

Alpha Beta Pruning 000000 Heuristic •00000000

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

# Static Evaluation Function

- A static board evaluation function is a heuristics to estimate the value of non-terminal states.
- It should reflect the player's chances of winning from that vertex.
- It should be easy to compute from the board configuration.

Alpha Beta Pruning 000000 Heuristic

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

# Evaluation Function Properties

- If the SBE for one player is x, then the SBE for the other player should be -x.
- The SBE should agree with the cost or reward at terminal vertices.

Heuristic

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

## Linear Evaluation Function Example

- For Chess, an example of an evaluation function can be a linear combination of the following variables.
- Material.
- Ø Mobility.
- Sking safety.
- Center control.
  - These are called the features of the board.

Alpha Beta Pruning 000000 Heuristic

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

## Iterative Deepening Search

- IDS could be used with SBE.
- In iteration *d*, the depth is limited to *d*, and the SBE of the non-terminal vertices are used as their cost or reward.

Alpha Beta Pruning 000000 Heuristic

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

## Non Linear Evaluation Function

- The SBE can be estimated given the features using a neural network.
- The features are constructed using domain knowledge, or a possibly a convolutional neural network.
- The training data are obtained from games between professional players.

Alpha Beta Pruning 000000 Heuristic

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

## Monte Carlo Tree Search

- Simulate random games by selecting random moves for both players.
- Exploitation by keeping track of average win rate for each successor from previous searches and picking the successors that lead to more wins.
- Exploration by allowing random choices of unvisited successors.

Alpha Beta Pruning 000000 Heuristic 0000000000

### Monte Carlo Tree Search Diagram

Discussion

Alpha Beta Pruning 000000 Heuristic

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

#### Upper Confidence Bound Discussion

• Combine exploitation and exploration by picking successors using upper confidence bound for tree.

$$\frac{w_s}{n_s} + c\sqrt{\frac{\log t}{n_s}}$$

- $w_s$  is the number of wins after successor s, and  $n_s$  the number of simulations after successor s, and t is the total number of simulations.
- Similar to the UCB algorithm for MAB.

Alpha Beta Pruning 000000 Heuristic 00000000

### Alpha GO Example

- MCTS with  $> 10^5$  play-outs.
- Deep neural network to compute SBE.
