#### Summary Discussion

- Applications
- Computer vision: SIFT, HOG, Haar.
- Computer vision: convolutional neural network.
- Natural language processing: N-gram.

# Natural Language

- Generative model: next lecture Bayesian network.
- This lecture: a review of probability, application in natural language.
- The goal is to estimate the probabilities of observing a sentence and use it to generate new sentences.

#### Tokenization Motivation

- When processing language, documents (called corpus) need to be turned into a sequence of tokens.
- Split the string by space and punctuations.
- Remove stopwords such as "the", "of", "a", "with" ...
- Solution Lower case all characters.
- Stemming or lemmatization words: make "looks", "looked", "looking" to "look".

#### Vocabulary Motivation

- Word token is an occurrence of a word.
- Word type is a unique token as a dictionary entry.
- Vocabulary is the set of word types.
- Characters can be used in place of words as tokens. In this case, the types are "a", "b", ..., "z", "", and vocabulary is the alphabet.

# Bag of Words Features

- Given a document *i* and vocabulary with size *m*, let *c<sub>ij</sub>* be the count of the word *j* in the document *i* for *j* = 1, 2, ..., *m*.
- Bag of words representation of a document has features that are the count of each word divided by the total number of words in the document.

$$x_{ij} = \frac{c_{ij}}{\sum\limits_{j'=1}^{m} c_{ij'}}$$

# TF IDF Features

• Another feature representation is called tf-idf, which stands for normalized term frequency, inverse document frequency.

$$tf_{ij} = \frac{c_{ij}}{\max_{j'} c_{ij'}}, idf_j = \log \frac{n}{\sum_{i=1}^n \mathbb{1}_{\{c_{ij} > 0\}}}$$
$$x_{ij} = tf_{ij} idf_j$$

 n is the total number of documents and <sup>n</sup> 1<sub>{cij>0}</sub> is the number of documents containing word j.

# Token Notations

- A word (or character) at position t of a sentence (or string) is denoted as  $z_t$ .
- A sentence (or string) with length d is  $(z_1, z_2, ..., z_d)$ .
- $\mathbb{P}\left\{Z_t = z_t\right\}$  is the probability of observing  $z_t \in \{1, 2, ..., j\}$  at position t of the sentence, usually shortened to  $\mathbb{P}\left\{z_t\right\}$ .

▲□▶▲圖▶▲≣▶▲≣▶ ≣ のQで 12/29

#### Unigram Model Definition

• Unigram models assume independence.

$$\mathbb{P}\left\{z_1, z_2, ..., z_d\right\} = \prod_{t=1}^d \mathbb{P}\left\{z_t\right\}$$

• For a sequence of words, independence means:  $\mathbb{P} \{z_t | z_{t-1}, z_{t-2}, ..., z_1\} = \mathbb{P} \{z_t\}$ 

<□ ▶ < □ ▶ < ■ ▶ < ■ ▶ < ■ ▶ ■ の < 0 13/29

### Maximum Likelihood Estimation

•  $\mathbb{P}\{z_t\}$  can be estimated by the count of the word  $z_t$ .

$$\hat{\mathbb{P}}\left\{z_t\right\} = \frac{c_{z_t}}{\sum\limits_{z=1}^{m} c_z}$$

 This is called the maximum likelihood estimator because it maximizes the probability of observing the sentences in the training set.

<□▶<□▶<□▶<■▶<≡▶<≡▶ ≡ のへで 14/29

#### MLE Example Definition

- Let  $p = \hat{\mathbb{P}} \{ 0 \}$  in a string with  $c_0 0$ 's and  $c_1 1$ 's.
- The probability of observing the string is:

$$\binom{c_0+c_1}{c_0}p^{c_0}(1-p)^{c_1}$$

• The above expression is maximized by:

$$p^{\star}=\frac{c_0}{c_0+c_1}$$

<□ ▶ < □ ▶ < ■ ▶ < ■ ▶ < ■ ▶ ■ の < 0 15/29

#### Bigram Model Definition

• Bigram models assume Markov property.

$$\mathbb{P}\{z_1, z_2, ..., z_d\} = \mathbb{P}\{z_1\} \prod_{t=2}^{d} \mathbb{P}\{z_t | z_{t-1}\}$$

• Markov property means the distribution of an element in the sequence only depends on the previous element.

$$\mathbb{P}\left\{z_{t}|z_{t-1}, z_{t-2}, ..., z_{1}\right\} = \mathbb{P}\left\{z_{t}|z_{t-1}\right\}$$

### Conditional Probability

• In general, the conditional probability of an event A given another event B is the probability of A and B occurring at the same time divided by the probability of event B.

$$\mathbb{P}\left\{A|B\right\} = \frac{\mathbb{P}\left\{AB\right\}}{\mathbb{P}\left\{B\right\}}$$

• For a sequence of words, the conditional probability of observing  $z_t$  given  $z_{t-1}$  is observed is the probability of observing both divided by the probability of observing  $z_{t-1}$  first.

$$\mathbb{P}\left\{z_t|z_{t-1}\right\} = \frac{\mathbb{P}\left\{z_{t-1}, z_t\right\}}{\mathbb{P}\left\{z_{t-1}\right\}}$$

<□ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ = の < ∩ 17/29

# Bigram Model Estimation

 Using the conditional probability formula, P {z<sub>t</sub>|z<sub>t-1</sub>}, called transition probabilities, can be estimated by counting all bigrams and unigrams.

$$\hat{\mathbb{P}}\left\{z_t | z_{t-1}\right\} = \frac{c_{z_{t-1}, z_t}}{c_{z_{t-1}}}$$

#### Transition Matrix Definition

$$\begin{bmatrix} \hat{\mathbb{P}} \{1|1\} & \hat{\mathbb{P}} \{2|1\} & \hat{\mathbb{P}} \{3|1\} \\ \hat{\mathbb{P}} \{1|2\} & \hat{\mathbb{P}} \{2|2\} & \hat{\mathbb{P}} \{3|2\} \\ \hat{\mathbb{P}} \{1|3\} & \hat{\mathbb{P}} \{2|3\} & \hat{\mathbb{P}} \{3|3\} \end{bmatrix}$$

• Given the initial distribution of tokens, the distribution of the next token can be found by multiplying it by the transition probabilities.

<□▶<□▶<□▶<三▶<=>> < => < => < = < 0 < 0 < 19/29

#### Aside: Stationary Probability Discussion

• Given the bigram model, the fraction of times a token occurs for a document with infinite length can be computed. The resulting distribution is called the stationary distribution.

$$p_{\infty} = p_0 M^{\infty}$$

<ロト</a>

# Aside: Spectral Decomposition

- It is easier to find powers of diagonal matrices.
- Let *D* be the diagonal matrix with eigenvalues of *M* on the diagonal and *P* be the matrix with columns being corresponding eigenvectors.

$$MP = \lambda_i P, i = 1, 2, ..., K$$

$$MP = PD$$

$$M = PDP^{-1}$$

$$M^n = \underbrace{PDP^{-1}PDP^{-1}...PDP^{-1}}_{n \text{ times}} = PD^nP^{-1}$$

$$M^{\infty} = PD^{\infty}P^{-1}$$

<□ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □ ▶ < □

### Aside: Stationarity

Discussion

• A simpler way to compute the stationary distribution is to solve the equation:

 $p_{\infty} = p_{\infty}M$ 

#### Trigram Model Definition

• The same formula can be applied to trigram: sequences of three tokens.

$$\hat{\mathbb{P}}\left\{z_{t}|z_{t-1}, z_{t-2}\right\} = \frac{c_{z_{t-2}, z_{t-1}, z_{t}}}{c_{z_{t-2}, z_{t-1}}}$$

• In a document, likely, these longer sequences of tokens never appear. In those cases, the probabilities are  $\frac{0}{0}$ . Because of this, Laplace smoothing adds 1 to all counts.

$$\hat{\mathbb{P}}\left\{z_{t}|z_{t-1}, z_{t-2}\right\} = \frac{c_{z_{t-2}, z_{t-1}, z_{t}} + 1}{c_{z_{t-2}, z_{t-1}} + m}$$

### Laplace Smoothing

• Laplace smoothing should be used for bigram and unigram models too.

$$\hat{\mathbb{P}} \{ z_t | z_{t-1} \} = \frac{c_{z_{t-1}, z_t} + 1}{c_{z_{t-1}} + m}$$
$$\hat{\mathbb{P}} \{ z_t \} = \frac{c_{z_t} + 1}{\sum_{z=1}^m c_z + m}$$

• Aside: Laplace smoothing can also be used in decision tree training to compute entropy.

# N Gram Model

- Input: series  $\{z_1, z_2, ..., z_{d_i}\}_{i=1}^n$ .
- Output: transition probabilities  $\hat{\mathbb{P}} \{z_t | z_{t-1}, z_{t-2}, ..., z_{t-N+1}\}$  for all  $z_t = 1, 2, ..., m$ .
- Compute the transition probabilities using counts and Laplace smoothing.

$$\hat{\mathbb{P}}\left\{z_{t}|z_{t-1}, z_{t-2}, \dots, z_{t-N+1}\right\} = \frac{c_{z_{t-N+1}, z_{t-N+2}, \dots, z_{t}} + 1}{c_{z_{t-N+1}, z_{t-N+2}, \dots, z_{t-1}} + m}$$

# Sampling from Discrete Distribution

- To generate new sentences given an *N* gram model, random realizations need to be generated given the conditional probability distribution.
- Given the first N − 1 words, z<sub>1</sub>, z<sub>2</sub>, ..., z<sub>N-1</sub>, the distribution of next word is approximated by p<sub>x</sub> = P {z<sub>N</sub> = x | z<sub>N-1</sub>, z<sub>N-2</sub>, ..., z<sub>1</sub>}. This process then can be repeated for on z<sub>2</sub>, z<sub>3</sub>, ..., z<sub>N-1</sub>, z<sub>N</sub> and so on.

### Inverse Transform Sampling, Part I

- Most programming languages have a function to generate a random number u ~ Unif [0,1].
- If there are m = 2 tokens in total and the conditional probabilities are p and 1 p. Then the following distributions are the same.

$$z_N = \begin{cases} 0 & \text{with probability } p \\ 1 & \text{with probability } 1 - p \end{cases} \Leftrightarrow z_N = \begin{cases} 0 & \text{if } 0 \leqslant u \leqslant p \\ 1 & \text{if } p < u \leqslant 1 \end{cases}$$

### Inverse Transform Sampling, Part *II*

• In the general case with *m* tokens with conditional probabilities  $p_1, p_2, ..., p_m$  with  $\sum_{j=1}^m p_j = 1$ . Then the following distributions are the same.

$$z_N = j$$
 with probability  $p_j \Leftrightarrow z_N = j$  if  $\sum_{j'=1}^{j-1} p_{j'} < u \leqslant \sum_{j'=1}^j p_{j'}$ 

• This can be used to generate a random token from the conditional distribution.

<□▶<週▶<≧▶<≧▶<≧▶<≧ のQで 28/29

#### Sparse Matrix Discussion

- The transition matrix is too large with mostly zeros.
- Usually, clustering is done so each type (or feature) represent a group of words.
- For the homework, treat each character (letter or space) as a token, then there are 26 + 1 types. All punctuations are removed or converted to spaces.

#### Summary Discussion

- Computer vision: SIFT, HOG, Haar.
- Computer vision: convolutional neural network.
- Natural language processing: N-gram.
- Natural language processing: Bayesian network (next time).
