## Supervised Learning

Motivation

- Given training data and label.
- Discriminative: estimate  $\hat{\mathbb{P}}\{Y=y|X=x\}$  to classify.
- Generative: estimate  $\hat{\mathbb{P}}\left\{X=x|Y=y\right\}$  and Bayes rule to classify.

## Naive Bayes

• Naive Bayes:  $X_i \leftarrow Y$ .

$$\begin{split} & \mathbb{P}\left\{Y = 1 | X_1 = x_1, ..., X_m = x_m\right\} \\ & = \frac{\mathbb{P}\left\{Y = 1\right\} \prod_{j=1}^{m} \mathbb{P}\left\{X_j = x_j | Y = 1\right\}}{\mathbb{P}\left\{X_1 = x_1, ..., X_m = x_m\right\}} \\ & = \frac{1}{1 + \exp\left(-\log\left(\frac{\mathbb{P}\left\{Y = 1\right\}}{\mathbb{P}\left\{Y = 0\right\}}\right) - \sum_{j=1}^{m}\log\left(\frac{\mathbb{P}\left\{X_j = x_j | Y = 1\right\}}{\mathbb{P}\left\{X_j = x_j | Y = 0\right\}}\right)\right)} \end{split}$$

### Logistic Regression

Motivation

1

$$\overline{1 + \exp\left(-\log\left(\frac{\mathbb{P}\left\{Y = 1\right\}}{\mathbb{P}\left\{Y = 0\right\}}\right) - \sum_{j=1}^{m}\log\left(\frac{\mathbb{P}\left\{X_{j} = x_{j}|Y = 1\right\}}{\mathbb{P}\left\{X_{j} = x_{j}|Y = 0\right\}}\right)\right)}$$

• Logistic Regression:  $X_i \rightarrow Y$ .

$$\tilde{\mathbb{P}} \left\{ Y = 1 | X_1 = x_1, ..., X_m = x_m \right\}$$

$$= \frac{1}{1 + \exp\left(-\left(b + \sum_{i=1}^m w_i x_i\right)\right)}$$

## Generative Adversarial Network

- Generative Adversarial Network (GAN): two competitive neural networks.
- Generative network input random noise and output fake images.
- ② Discriminative network input real and fake images and output label real or fake.

# Generative Adversarial Network Diagram Motivation

## **Unsupervised Learning**

#### Motivation

- Supervised learning:  $(x_1, y_1), (x_2, y_2), ..., (x_n, y_n)$ .
- Unsupervised learning:  $x_1, x_2, ..., x_n$ .
- There are a few common tasks without labels.
- Olustering: separate instances into groups.
- Novelty (outlier) detection: find instances that are different.
- Oimensionality reduction: represent each instance with a lower dimensional feature vector while maintaining key characteristics.

# Unsupervised Learning Applications Motivation

- Google News
- Google Photo
- Image Segmentation
- Text Processing

### Hierarchical Clustering Description

- Start with each instance as a cluster.
- Merge clusters that are closest to each other.
- Result in a binary tree with close clusters as children.

# Hierarchical Clustering Diagram Description

### Clusters

#### Definition

A cluster is a set of instances.

$$C_k \subseteq \{x_i\}_{i=1}^n$$

A clustering is a partition of the set of instances into clusters.

$$C = C_1, C_2, ..., C_K$$

$$C_k \cap C_{k'} = \emptyset \text{ for } k' \neq k, \bigcup_{i=1}^K C_k = \{x_i\}_{i=1}^n$$

## Distance between Points

Definition

• Usually, the distance between two instances is measured by the Euclidean distance or *L*<sub>2</sub> distance.

$$d(x_{i}, x_{i'}) = \|x_{i} - x_{i'}\|_{2} = \sqrt{\sum_{j=1}^{m} (x_{ij} - x_{i'j})^{2}}$$

• Other examples include:  $L_1$  distance and  $L_{\infty}$  distance.

$$d_{1}(x_{i}, x_{i'}) = \|x_{i} - x_{i'}\|_{1} = \sum_{j=1}^{m} |x_{ij} - x_{i'j}|$$

$$d_{\infty}(x_{i}, x_{i'}) = \|x_{i} - x_{i'}\|_{\infty} = \max_{j=1,2,...,m} \{|x_{ij} - x_{i'j}|\}$$

## Single Linkage Distance

 Usually, the distance between two clusters is measured by the single-linkage distance.

$$d(C_k, C_{k'}) = \min \{d(x_i, x_{i'}) : x_i \in C_k, x_{i'} \in C_{k'}\}$$

• It is the shortest distance from any instance in one cluster to any instance in the other cluster.

## Complete Linkage Distance

• Another measure is complete-linkage distance,

$$d(C_k, C_{k'}) = \max\{d(x_i, x_{i'}) : x_i \in C_k, x_{i'} \in C_{k'}\}$$

• It is the longest distance from any instance in one cluster to any instance in the other cluster.

## Average Linkage Distance Diagram

• Another measure is average-linkage distance.

$$d(C_k, C_{k'}) = \frac{1}{|C_k| |C_{k'}|} \sum_{x_i \in C_k, x_{i'} \in C_{k'}} d(x_i, x_{i'})$$

• It is the average distance from any instance in one cluster to any instance in the other cluster.

### Hierarchical Clustering

#### Algorithm

- Input: instances:  $\{x_i\}_{i=1}^n$ , the number of clusters K, and a distance function d.
- Output: a list of clusters  $C = C_1, C_2, ..., C_K$ .
- Initialize for t = 0.

$$C^{(0)} = C_1^{(0)}, ..., C_n^{(0)}, \text{ where } C_k^{(0)} = \{x_k\}, k = 1, 2, ..., n\}$$

• Loop for t = 1, 2, ..., n - k + 1.

$$\begin{split} (k_1^{\star}, k_2^{\star}) &= \operatorname*{argmin}_{k_1, k_2} d\left(C_{k_1}^{(t-1)}, C_{k_2}^{(t-1)}\right) \\ C^{(t)} &= \left(C_{k_1^{\star}}^{(t-1)} \cup C_{k_2^{\star}}^{(t-1)}\right), C_1^{(t-1)}, \dots \text{ no } k_1^{\star}, k_2^{\star} \dots, C_n^{(t-1)} \end{split}$$

### Number of Clusters

#### Discussion

- K can be chosen using prior knowledge about X.
- The algorithm can stop merging as soon as all the between-cluster distances are larger than some fixed R.
- The binary tree generated in the process is often called dendrogram, or taxonomy, or a hierarchy of data points.
- An example of a dendrogram is the tree of life in biology.

# K Means Clustering Description

- This is not K Nearest Neighbor.
- Start with random cluster centers.
- Assign each point to its closest center.
- Update all cluster centers as the center of its points.

# Center Definition

• The center is the average of the instances in the cluster,

$$c_k = \frac{1}{|C_k|} \sum_{x \in C_k} x$$

## Distortion Distortion

- Distortion for a point is the distance from the point to its cluster center.
- Total distortion is the sum of distortion for all points.

$$D_{K} = \sum_{i=1}^{n} d\left(x_{i}, c_{k^{*}(x_{i})}\left(x_{i}\right)\right)$$
$$k^{*}\left(x\right) = \operatorname*{argmin}_{k=1,2,...K} d\left(x, c_{k}\right)$$

## **Objective Function**

Definition

• When using Euclidean distance, sometimes total distortion is defined as sum of squared distances.

$$D_K = \sum_{i=1}^n d_2(x_i, c_{k^*(x_i)}(x_i))^2$$

- This algorithm stop in finite steps.
- This algorithm is trying to minimize the total distortion but fails.

## **Gradient Descent**

#### Definition

 When d is the Euclidean distance. K Means algorithm is the gradient descent when distortion is the objective (cost) function.

$$\frac{\partial}{\partial c_k} \sum_{k=1}^K \sum_{x \in C_k} \|x - c_k\|_2^2 = 0$$

$$\Rightarrow -2 \sum_{x \in C_k} (x - c_k) = 0$$

$$\Rightarrow c_k = \frac{1}{|C_k|} \sum_{x \in C_k} x$$

## K Means Clustering

#### Algorithm

- Input: instances:  $\{x_i\}_{i=1}^n$ , the number of clusters K, and a distance function d.
- Output: a list of clusters  $C = C_1, C_2, ..., C_K$ .
- Initialize t = 0.  $c_L^{(0)} = K$  random points
- Loop until  $c^{(t)} = c^{(t-1)}$ .

$$C_{k}^{(t-1)} = \left\{ x : k = \underset{k' \in 1, 2, \dots, K}{\operatorname{argmin}} d\left(x, c_{k}^{(t-1)}\right) \right\}$$
$$c_{k}^{(t)} = \frac{1}{\left|C_{k}^{(t-1)}\right|} \sum_{x \in C_{k}^{(t-1)}} x$$

### Number of Clusters

#### Discussion

- There are a few ways to pick the number of clusters K.
- ullet K can be chosen using prior knowledge about X.
- ② K can be the one that minimizes distortion? No, when K = n, distortion = 0.
- ullet K can be the one that minimizes distortion + regularizer.

$$K^* = \underset{k}{\operatorname{argmin}} (D_k + \lambda \cdot m \cdot k \cdot \log n)$$

•  $\lambda$  is a fixed constant chosen arbitrarily.

### Initial Clusters

#### Discussion

- There are a few ways to initialize the clusters.
- K uniform random points in  $\{x_i\}_{i=1}^n$ .
- ② 1 uniform random point in  $\{x_i\}_{i=1}^n$  as  $c_1^{(0)}$ , then find the farthest point in  $\{x_i\}_{i=1}^n$  from  $c_1^{(0)}$  as  $c_2^{(0)}$ , and find the farthest point in  $\{x_i\}_{i=1}^n$  from the closer of  $c_1^{(0)}$  and  $c_2^{(0)}$  as  $c_3^{(0)}$ , and repeat this K times.

### Gaussian Mixture Model

#### Discussion

- In K means, each instance belong to one cluster with certainty.
- One continuous version is called the Gaussian mixture model: each instance belongs to one of the clusters with a positive probability.
- The model can be trained using Expectation Maximization Algorithm (EM Algorithm).

### EM Algorithm, Part I

Discussion

• The means  $\mu_k$  and variances  $\sigma_k^2$  for each cluster need to be trained. The mixing probability  $\pi_k$  also needs to be trained.

$$(\mu_1, \sigma_1^2, \pi_1), (\mu_2, \sigma_2^2, \pi_2), ..., (\mu_K, \sigma_K^2, \pi_K)$$

• Initialize by random guesses of clusters means and variances.

### EM Algorithm, Part II

Discussion

• Expectation Step. Compute responsibilities for i = 1, 2, ..., n and k = 1, 2, ..., K.

$$\hat{\gamma}_{i,k} = \frac{\hat{\pi}_{k} \varphi_{k} (x_{i})}{\sum_{k'=1,2,\dots,K} \hat{\pi}_{k'} \varphi_{k'} (x_{i})}$$

$$\varphi_k(x) = \frac{1}{\sqrt{2\pi}\hat{\sigma}_k} \exp\left(-\frac{(x-\hat{\mu}_k)^2}{2\hat{\sigma}_k^2}\right)$$

### EM Algorithm, Part III

Discussion

• Maximization Step. Compute means and variances for each k = 1, 2, ..., K.

$$\hat{\mu}_k = \frac{\sum\limits_{i=1}^n \hat{\gamma}_{i,k} x_i}{\sum\limits_{i=1}^n \hat{\gamma}_i}, \text{ and } \hat{\sigma}_k^2 = \frac{\sum\limits_{i=1}^n \hat{\gamma}_{i,k} \left(x_i - \hat{\mu}_k\right)^2}{\sum\limits_{i=1}^n \hat{\gamma}_i}$$

$$\hat{\pi}_k = \frac{1}{n} \sum\limits_{i=1}^n \hat{\gamma}_{i,k}$$

• Repeat until convergent.
