# Uninformed vs. Informed Search

## Motivation

- Uninformed search means only the goal  $G$  and the successor functions  $s'$  are given.
- Informed search means which non-goal states are better is also known.

# Heuristic

## Motivation

- The additional information is usually given as a heuristic cost from a state  $s$  to the goal.
- The cost of the path from the start to a vertex  $s$  in the frontier is  $g(s)$ .
- The cost from  $s$  to the goal,  $h^*(s)$ , is estimated by  $h(s)$ . This estimate may not be accurate.

$$h(s) \approx h^*(s)$$

# Uniform Cost Search

## Description

- Expand the vertices with the lowest current path cost  $g(s)$  first.
- It is BFS with a priority queue based on  $g(s)$ .
- It is equivalent to BFS if  $c = 1$  is constant on all edges.
- It is also called Dijkstra's Algorithm.

# Uniform Cost Search

## Algorithm

- Input: a weighted digraph  $(V, E, c)$ , initial states  $I$  and goal states  $G$ .
- Output: a path from  $I$  to  $G$ .
- EnQueue initial states into a priority queue  $Q$ . Here,  $Q$  is ordered by  $g(s)$  for  $s \in Q$ .

$$Q = I$$

- While  $Q$  is not empty and goal is not deQueued, deQueue  $Q$  and enQueue its successors.

$$s = Q_{(0)} = \operatorname{argmin}_{s \in Q} g(s)$$

$$Q = Q + s'(s)$$

# Uniform Cost Search Performance

## Discussion

- UCS is complete.
- UCS is optimal with any  $c$ .

# Best First Greedy Search

## Description

- Expand the vertices with the lowest heuristic cost  $h(s)$  first.
- Use a priority queue based on  $h(s)$ .
- BFGS is not an abbreviation of Best First Greedy Search: BFGS is the Broyden Fletcher Goldfarb Shanno algorithm (a version of gradient descent).

# Best First Greedy Search

## Algorithm

- Input: a weighted digraph  $(V, E, c)$ , initial states  $I$  and goal states  $G$ , and the heuristic function  $h(s), s \in V$ .
- Output: a path from  $I$  to  $G$ .
- EnQueue initial states into a priority queue  $Q$ . Here,  $Q$  is ordered by  $h(s)$  for  $s \in Q$ .

$$Q = I$$

- While  $Q$  is not empty and goal is not deQueued, deQueue  $Q$  and enQueue its successors.

$$s = Q_{(0)} = \operatorname{argmin}_{s \in Q} h(s)$$

$$Q = Q + s'(s)$$

# Best First Greedy Search Performance

## Discussion

- Greedy is incomplete.
- Greedy is not optimal.

# A Search

## Description

- Expand the vertices with the lowest total cost  $g(s) + h(s)$  first.
- Use a priority queue based on  $g(s) + h(s)$ .
- A stands for Always be optimistic?

# A Search

## Algorithm

- Input: a weighted digraph  $(V, E, c)$ , initial states  $I$  and goal states  $G$ , and the heuristic function  $h(s)$ ,  $s \in V$ .
- Output: a path from  $I$  to  $G$ .
- EnQueue initial states into a priority queue  $Q$ . Here,  $Q$  is ordered by  $g(s) + h(s)$  for  $s \in Q$ .

$$Q = I$$

- While  $Q$  is not empty and goal is not deQueued, deQueue  $Q$  and enQueue its successors.

$$s = Q_{(0)} = \operatorname{argmin}_{s \in Q} g(s) + h(s)$$

$$Q = Q + s'(s)$$

# A Search Performance

## Discussion

- A is complete.
- A is not optimal.

# A Star Search

## Description

- $A^*$  search is A search with an admissible heuristic.

# Admissible Heuristic

## Definition

- A heuristic is admissible if it never over estimates the true cost.

$$0 \leq h(s) \leq h^*(s)$$

# Dominated Heuristic

## Definition

- One heuristic,  $h_1$ , is dominated by another,  $h_2$ , if:

$$h_1(s) \leq h_2(s) \leq h^*(s), \forall s \in S$$

- If  $h_2$  dominates  $h_1$ , then  $h_2$  is better than  $h_1$  since  $A^*$  using  $h_1$  expands at least as many states (or more) than  $A^*$  using  $h_2$ .
- If  $h_2$  dominated  $h_1$ ,  $A^*$  with  $h_2$  is better informed than  $A^*$  with  $h_1$ .

# Non-Optimal Heuristic

## Definition

- If optimality is not required and a satisfying solution is acceptable, then the heuristic should be as close as possible, either under or over, to the actual cost.
- This results in fewer states being expanded compared to using poor but admissible heuristics.

# A Star Search with Revisit, Part I

## Algorithm

- Input: a weighted digraph  $(V, E, c)$ , initial states  $I$  and goal states  $G$ , and the heuristic function  $h(s)$ ,  $s \in V$ .
- Output: a path with minimum cost from  $I$  to  $G$ .
- EnQueue initial states into a priority queue  $Q$ . Here,  $Q$  is ordered by  $g(s) + h(s)$  for  $s \in Q$ .

$$Q = I$$

$$g(I) = 0$$

$$g(s) = \infty, \text{ for } s \notin I$$

- Initialize the list of visited vertices,  $P$ .

$$P = \emptyset$$

# A Star Search with Revisit, Part II

## Algorithm

- While  $Q$  is not empty and goal is not deQueued, deQueue  $Q$ , put it on  $P$  and enQueue its successors to  $Q$ , and update the cost functions.

$$s = Q_{(0)} = \operatorname{argmin}_{s \in Q} g(s) + h(s)$$

$$P = P + s$$

$$Q = Q + s'(s), \text{ update } g(s') = \min \{g(s'), g(s) + c(s, s')\}$$

# A Search Performance

## Discussion

- $A^*$  is complete.
- $A^*$  is optimal.

# Iterative Deepening A Star Search

## Discussion

- $A^*$  can use a lot of memory.
- Do path checking without expanding any vertex with  $g(s) + h(s) > 1$ .
- Do path checking without expanding any vertex with  $g(s) + h(s) > 2$ .
- ...
- Do path checking without expanding any vertex with  $g(s) + h(s) > d$ .

# Iterative Deepening A Star Search Performance

## Discussion

- IDA\* is complete.
- IDA\* is optimal.
- IDA\* is more costly than  $A^*$ .

# Beam Search

## Discussion

- Version 1: Keep a priority queue with fixed size  $k$ . Only keep the top  $k$  vertices and discard the rest.
- Version 2: Only keep the vertices that are at most  $\epsilon$  worse than the best vertex in the queue.  $\epsilon$  is called the beam width.

# Beam Search Performance

## Discussion

- Beam is incomplete.
- Beam is not optimal.
