Alpha Beta Pruning 00000 Heuristic 00000000

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Game Tree Motivation

- The initial state is the beginning of the game.
- There are no goal states, but there are multiple terminal states in which the game ends.
- Each successor of a state represents a feasible action (or a move) in the game.
- The search problem is to find the terminal state with the lowest cost (or usually the highest reward).

Alpha Beta Pruning 00000 Heuristic 00000000

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Adversarial Search

- The main difference between finding solutions of games and standard search problems or local search problems is that part of the search is performed by an opponent adversarially.
- Usually, the opponent wants to maximize the cost or minimize the reward from the search. This type of search problems is called adversarial search.
- In game theory, the solution of a game is called an equilibrium. It is a path in which both players do not want to change actions.

Alpha Beta Pruning 00000 Heuristic 00000000

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Backward Induction

- Games are usually solved backward starting from the terminal states.
- Each player chooses the best action (successor) given the (already solved) optimal actions of all players in the subtrees (called subgames).

Alpha Beta Pruning 00000 Heuristic 00000000

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Zero-Sum Games

- If the sum of the reward or cost over all players at each terminal state is 0, the game is called a zero-sum game.
- Usually, for games with one winner: the reward for winning and the cost of losing are both 1. If the game ends with a tie, both players get 0.

Minimax Algorithm Description

• Use DFS on the game tree.

Alpha Beta Pruning 00000 Heuristic 00000000

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Minimax Algorithm

- Input: a game tree (V, E, c), and the current state s.
- Output: the value of the game at *s*.
- If s is a terminal state, return c(s).
- If the player is MAX, return the maximum value over all successors.

$$\alpha\left(\boldsymbol{s}\right) = \max_{\boldsymbol{s}' \in \boldsymbol{s}'\left(\boldsymbol{s}\right)} \beta\left(\boldsymbol{s}'\right)$$

• If the player is MIN, return the minimum value over all successors.

$$\beta\left(s\right) = \min_{s' \in s'(s)} \alpha\left(s'\right)$$

Alpha Beta Pruning 00000 Heuristic 00000000

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Backtracking Discussion

• The optimal actions (solution paths) can be found by backtracking from all terminal states as in DFS.

$$s^{\star}(s) = \underset{s' \in s'(s)}{\operatorname{argmax}} \beta(s') \text{ for MAX}$$
$$s^{\star}(s) = \underset{s' \in s'(s)}{\operatorname{argmin}} \alpha(s') \text{ for MIN}$$

Alpha Beta Pruning 00000 Heuristic 00000000

▲ロト ▲周ト ▲ヨト ▲ヨト ヨー のくで

Minimax Performance

• The time and space complexity is the same as DFS. Note that D = d is the maximum depth of the terminal states.

$$T = 1 + b + b^2 + \dots + b^d$$
$$S = (b - 1) \cdot d$$

Alpha Beta Pruning 00000 Heuristic 00000000

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Non-deterministic Game

- For non-deterministic games in which chance can make a move (dice roll or coin flip), use expected reward or cost instead.
- The algorithm is also called expectiminimax.

Alpha Beta Pruning •0000 Heuristic 00000000

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Pruning Motivation

- Time complexity is a problem because the computer usually has a limited amount of time to "think" and make a move.
- It is possible to reduce the time complexity by removing the branches that will not lead the current player to win. It is called the Alpha-Beta pruning.

Alpha Beta Pruning 00000 Heuristic 00000000

Alpha Beta Pruning Description

- \bullet During DFS, keep track of both α and β for each vertex.
- Prune the subtree with $\alpha \ge \beta$.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Alpha Beta Pruning Algorithm, Part I Algorithm

- Input: a game tree (V, E, c), and the current state s.
- Output: the value of the game at *s*.
- If s is a terminal state, return c(s).

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Alpha Beta Pruning Algorithm, Part II Algorithm

If the player is MAX, return the maximum value over all successors.

$$\alpha (s) = \max_{s' \in s'(s)} \beta (s')$$
$$\beta (s) = \beta (\text{ parent } (s))$$

- Stop and return β if $\alpha \ge \beta$.
- If the player is MIN, return the minimum value over all successors.

$$\beta(s) = \min_{s' \in s'(s)} \alpha(s')$$
$$\alpha(s) = \alpha(\text{ parent } (s))$$

• Stop and return α if $\alpha \ge \beta$.

Alpha Beta Pruning

Heuristic 00000000

Alpha Beta Performance

- In the best case, the best action of each player is the leftmost child.
- In the worst case, Alpha Beta is the same as minimax.

Static Evaluation Function

- A static board evaluation function is a heuristics to estimate the value of non-terminal states.
- It should reflect the player's chances of winning from that vertex.
- It should be easy to compute from the board configuration.

Alpha Beta Pruning 00000 Heuristic

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Evaluation Function Properties Definition

- If the SBE for one player is *x*, then the SBE for the other player should be -x.
- The SBE should agree with the cost or reward at terminal vertices.

Heuristic

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Linear Evaluation Function Example

- For Chess, an example of an evaluation function can be a linear combination of the following variables.
- Material.
- Ø Mobility.
- Sking safety.
- Center control.
- These are called the features of the board.

Alpha Beta Pruning 00000 Heuristic

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Iterative Deepening Search

- IDS could be used with SBE.
- In iteration *d*, the depth is limited to *d*, and the SBE of the non-terminal vertices are used as their cost or reward.

Heuristic

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Non Linear Evaluation Function

- The SBE can be estimated given the features using a neural network.
- The features are constructed using domain knowledge, or a possibly a convolutional neural network.
- The training data are obtained from games between professional players.

Alpha Beta Pruning 00000 Heuristic

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Monte Carlo Tree Search

- Simulate random games by selecting random moves for both players.
- Exploitation by keeping track of average win rate for each successor from previous searches and picking the successors that lead to more wins.
- Exploration by allowing random choices of unvisited successors.

Alpha Beta Pruning 00000 Heuristic

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Upper Confidence Bound Discussion

• Combine exploitation and exploration by picking successors using upper confidence bound for tree.

$$\frac{w_s}{n_s} + c \sqrt{\frac{\log t}{n_s}}$$

- w_s is the number of wins after successor s, and n_s the number of simulations after successor s, and t is the total number of simulations.
- Similar to the UCB algorithm for MAB.

Alpha Beta Pruning 00000 Heuristic 0000000

Alpha GO Example

- MCTS with $>10^5$ play-outs.
- Convolutional neural network to compute SBE.
