#### Zero-One Loss Function

#### Motivation

• An objective function is needed to select the "best"  $\hat{f}$ . An example is the zero-one loss.

$$\hat{f} = \underset{f}{\operatorname{argmin}} \sum_{i=1}^{n} \mathbb{1}_{\{f(x_i) \neq y_i\}}$$

- $\operatorname{argmin}_f$  objective (f) outputs the function that minimizes the objective.
- The objective function is called the cost function (or the loss function), and the objective is to minimize the cost.

### Squared Loss Function

#### Motivation

- Zero-one loss counts the number of mistakes made by the classifier. The best classifier is the one that makes the fewest mistakes.
- Another example is the squared distance between the predicted and the actual y value:

$$\hat{f} = \underset{f}{\operatorname{argmin}} \frac{1}{2} \sum_{i=1}^{n} (f(x_i) - y_i)^2$$

## Hypothesis Space

- There are too many functions to choose from.
- There should be a smaller set of functions to choose  $\hat{f}$  from.

$$\hat{f} = \underset{f \in \mathcal{H}}{\operatorname{argmin}} \frac{1}{2} \sum_{i=1}^{n} (f(x_i) - y_i)^2$$

ullet The set  ${\cal H}$  is called the hypothesis space.

### Linear Regression

Motivation

ullet For example,  ${\cal H}$  can be the set of linear functions. Then the problem can be rewritten in terms of the weights.

$$(\hat{w}_1, ..., \hat{w}_m, \hat{b}) = \underset{w_1, ..., w_m, b}{\operatorname{argmin}} \frac{1}{2} \sum_{i=1}^n (a_i - y_i)^2$$
where  $a_i = w_1 x_{i1} + w_2 x_{i2} + ... + w_m x_{im} + b$ 

• The problem is called (least squares) linear regression.

### Binary Classification Motivation

- If the problem is binary classification, *y* is either 0 or 1, and linear regression is not a great choice.
- This is because if the prediction is either too large or too small, the prediction is correct, but the cost is large.

#### **Activation Function**

#### Motivation

• Suppose  $\mathcal H$  is the set of functions that are compositions between another function g and linear functions.

$$\left(\hat{w}, \hat{b}\right) = \underset{w,b}{\operatorname{argmin}} \frac{1}{2} \sum_{i=1}^{n} \left(a_{i} - y_{i}\right)^{2}$$
where  $a_{i} = g\left(w^{T}x + b\right)$ 

• g is called the activation function.

# Linear Threshold Unit

 One simple choice is to use the step function as the activation function:

$$g\left(\begin{array}{c} \bullet \end{array}\right) = \mathbb{1}_{\left\{\begin{array}{c} \bullet \\ \bullet \end{array}\right\}} = \left\{\begin{array}{cc} 1 & \text{if } \bigcirc \geqslant 0 \\ 0 & \text{if } \bigcirc < 0 \end{array}\right.$$

• This activation function is called linear threshold unit (LTU).

### Sigmoid Activation Function

• When the activation function g is the sigmoid function, the problem is called logistic regression.

$$g\left(\boxed{\cdot}\right) = \frac{1}{1 + \exp\left(-\boxed{\cdot}\right)}$$

• This g is also called the logistic function.

### Cross-Entropy Loss Function

 The cost function used for logistic regression is usually the log cost function.

$$C(f) = -\sum_{i=1}^{n} (y_i \log (f(x_i)) + (1 - y_i) \log (1 - f(x_i)))$$

• It is also called the cross-entropy loss function.

### Logistic Regression Objective

 The logistic regression problem can be summarized as the following.

$$\left(\hat{w}, \hat{b}\right) = \underset{w,b}{\operatorname{argmin}} - \sum_{i=1}^{n} \left(y_i \log \left(a_i\right) + \left(1 - y_i\right) \log \left(1 - a_i\right)\right)$$
where  $a_i = \frac{1}{1 + \exp\left(-z_i\right)}$  and  $z_i = w^T x_i + b$ 

# Logistic Regression Description

- Initialize random weights.
- Evaluate the activation function.
- Compute the gradient of the cost function with respect to each weight and bias.
- Update the weights and biases using gradient descent.
- Repeat until convergent.

## Gradient Descent Intuition Definition

- If a small increase in  $w_1$  causes the distances from the points to the regression line to decrease: increase  $w_1$ .
- If a small increase in  $w_1$  causes the distances from the points to the regression line to increase: decrease  $w_1$
- The change in distance due to change in  $w_1$  is the derivative.
- The change in distance due to change in  $\begin{bmatrix} w \\ b \end{bmatrix}$  is the gradient.

#### Gradient

#### Definition

- The gradient is the vector of derivatives.
- The gradient of

$$f(x_i) = w^T x_i + b = w_1 x_{i1} + w_2 x_{i2} + ... + w_m x_{im} + b$$
 is:

$$\nabla_{w} f = \begin{bmatrix} \frac{\partial f}{\partial w_{1}} \\ \frac{\partial f}{\partial w_{2}} \\ \dots \\ \frac{\partial f}{\partial w_{m}} \end{bmatrix} = \begin{bmatrix} x_{i1} \\ x_{i2} \\ \dots \\ x_{im} \end{bmatrix} = x_{i}$$

$$\nabla_b f = 1$$

#### Chain Rule

#### Definition

• The gradient of  $f(x_i) = g(w^Tx_i + b) = g(w_1x_{i1} + w_2x_{i2} + ... + w_mx_{im} + b)$  can be found using the chain rule.

$$\nabla_{w} f = g' \left( w^{T} x_{i} + b \right) x_{i}$$
$$\nabla_{b} f = g' \left( w^{T} x_{i} + b \right)$$

• In particular, for the logistic function g:

$$g\left(\boxed{\cdot}\right) = \frac{1}{1 + \exp\left(-\boxed{\cdot}\right)}$$
$$g'\left(\boxed{\cdot}\right) = g\left(\boxed{\cdot}\right)\left(1 - g\left(\boxed{\cdot}\right)\right)$$

### Gradient Descent Step

Definition

• For logistic regression, use chain rule twice.

$$w = w - \alpha \sum_{i=1}^{n} (a_i - y_i) x_i$$

$$b = b - \alpha \sum_{i=1}^{n} (a_i - y_i)$$

$$a_i = g\left(w^T x_i + b\right), g\left(\overline{\cdot}\right) = \frac{1}{1 + \exp\left(-\overline{\cdot}\right)}$$

 $oldsymbol{lpha}$  is the learning rate. It is the step size for each step of gradient descent.

## Perceptron Algorithm Definition

• Update weights using the following rule.

$$w = w - \alpha (a_i - y_i) x_i$$
  

$$b = b - \alpha (a_i - y_i)$$
  

$$a_i = \mathbb{1}_{\{w^T x_i + b \ge 0\}}$$

# Logistic Regression, Part 1 Algorithm

- Inputs: instances:  $\{x_i\}_{i=1}^n$  and  $\{y_i\}_{i=1}^n$
- Outputs: weights and biases:  $w_1, w_2, ..., w_m$  and b
- Initialize the weights.

$$w_1, ..., w_m, b \sim \text{Unif } [-1, 1]$$

Evaluate the activation function.

$$a_i = g\left(w^T x_i + b\right), g\left(\boxed{\cdot}\right) = \frac{1}{1 + \exp\left(-\boxed{\cdot}\right)}$$

# Logistic Regression, Part 2

• Update the weights and bias using gradient descent.

$$w = w - \alpha \sum_{i=1}^{n} (a_i - y_i) x_i$$
$$b = b - \alpha \sum_{i=1}^{n} (a_i - y_i)$$

• Repeat the process until convergent.

$$|C - C|^{\mathsf{prev}}| < \varepsilon$$

### Stopping Rule and Local Minimum

Discussion

- Start with multiple random weights.
- Use smaller or decreasing learning rates. One popular choice is  $\frac{\alpha}{\sqrt{t}}$ , where t is the iteration count.
- Use the solution with the lowest *C*.

### Regression vs Classification

Discussion

- Logistic regression is usually used to solve classification problems (y is discrete or categorical), not regression problems (y is continuous).
- This course (and machine learning in general) will focus on solving classification problems.

### Other Non-linear Activation Function

- Activation function:  $g(\boxed{\cdot}) = \tanh(\boxed{\cdot}) = \frac{e^{\boxed{\cdot}} e^{-\boxed{\cdot}}}{e^{\boxed{\cdot}} + e^{-\boxed{\cdot}}}$
- Activation function:  $g(\overline{\ }) = \arctan(\overline{\ })$
- Activation function (rectified linear unit):  $g\left(\boxed{\cdot}\right) = \boxed{1}_{\left\{\boxed{\cdot}\right\} > 0}$
- All these functions lead to objective functions that are convex and differentiable (almost everywhere). Gradient descent can be used.

## Convexity

- If a function is convex, gradient descent with any initialization will converge to the global minimum (given sufficiently small learning rate).
- If a function is not convex, gradient descent with different initializations may converge to different local minima.
- A twice differentiable function is convex if and only its second derivative is non-negative.
- In the multivariate case, it means the Hessian matrix is positive semidefinite.

#### Positive Semidefinite

Discussion

Hessian matrix is the matrix of second derivatives:

$$H: H_{ij} = \frac{\partial^2 f}{\partial x_i \partial x_j}$$

- A matrix H is positive semidefinite if  $x^T H x \ge 0 \forall x \in \mathbb{R}^n$ .
- A symmetric matrix is positive semidefinite if and only if all of its eigenvalues are non-negative.
