## SIFT and HOG Features

- SIFT and HOG features are expensive to compute.
- Simpler features should be used for real-time face detection tasks.

Convolutional Neural Network

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

### Real-Time Face Detection

- Each image contains 10000 to 500000 locations and scales.
- Faces occur in 0 to 50 per image.
- Want a very small number of false positives.

## Haar Features

• Haar features are differences between sums of pixel intensities in rectangular regions. Some examples include convolution with the following filters.

$$\begin{bmatrix} 1 & 1 \\ -1 & -1 \end{bmatrix}, \begin{bmatrix} 1 & -1 \\ 1 & -1 \end{bmatrix}, \begin{bmatrix} 1 & -1 & 1 \\ 1 & -1 & 1 \end{bmatrix}, \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} \cdots$$

Convolutional Neural Network

# Weak Classifiers

• Each weak classifier is a decision stump (decision tree with only one split) using one Haar feature *x*.

$$f(x) = \mathbb{1}_{\{x > \theta\}}$$

 Finding the threshold by comparing the information gain from all possible splits is too expensive, so θ is usually computed as the average of the mean values of the feature for each class.

$$\theta = \frac{1}{2} \left( \frac{1}{n_0} \sum_{i:y_i=0} x_i + \frac{1}{n_1} \sum_{i:y_i=1} x_i \right)$$

Convolutional Neural Network

### Strong Classifiers

- The weak classifiers are trained sequentially using ensemble methods such as AdaBoost.
- A sequence of T weak classifiers is called aT -strong classifier.
- Multiple *T* -strong classifiers can be trained for different values of *T* and combined into a cascaded classifier.

Convolutional Neural Network

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

### Cascaded Classifiers

- Start with *aT* -strong classifier with small *T*, and use it reject obviously negative regions (regions with no faces).
- Train and use *aT* -strong classifier with larger *T* on only the regions that are not rejected.
- Repeat this process with stronger classifiers.

Convolutional Neural Network

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

#### Cascading Definition

- For example, at *T* = 1, the classifier achieves *a*100 percent detection rate and *a*50 percent false-positive rate.
- At T = 5, the classifier achieves a100 percent detection rate and a40 percent false-positive rate.
- At *T* = 20, the classifier achieves *a*100 percent detection rate and *a*10 percent false-positive rate.
- The result is a cascaded classifier with 100 percent detection rate and  $0.5 \cdot 0.4 \cdot 0.1 = 2$  percent false positive rate.

### Learning Convolution

• The convolution filters used to obtain the features can be learned in a neural network. Such networks are called convolutional neural networks and they usually contain multiple convolutional layers with fully connected and softmax layers near the end.

Convolutional Neural Network

### Convolutional Layers

• In the (fully connected) neural networks discussed previously, each input unit is associated with a different weight.

$$a = g\left(w^T x + b\right)$$

 In the convolutional layers, one single filter (a multi-dimensional array of weights) is used for all units (arranged in an array the same size as the filter).

$$A = g\left(W * X + b\right)$$

#### Pooling Definition

Combine the output of the convolution by max pooling,
a = max {x<sub>1</sub>...x<sub>m</sub>}

• Combine the output of the convolution by average pooling,

$$a = \frac{1}{m} \sum_{j=1}^{m} x_j$$

#### Training Convolutional Neural Networks, Part I Discussion

- The training is done by gradient descent.
- The gradient for the convolutional layers with respect to the filter weights is the convolution between the inputs to that layer and the output gradient from the next layer.

$$\frac{\partial C}{\partial W} = X * \frac{\partial C}{\partial O}$$

• The gradient for the convolutional layers with respect to the inputs is the convolution between the 180 degrees rotated filter and the output gradient from the next layer.

$$\frac{\partial C}{\partial X} = \operatorname{rot} W * \frac{\partial C}{\partial O}$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

#### Training Convolutional Neural Networks, Part II Discussion

- There are usually no weights in the pooling layers.
- The gradient for the max-pooling layers is 1 for the maximum input unit and 0 for all other units.
- The gradient for the average pooling layers is  $\frac{1}{m}$  for each of the *m* units.
