Supervised Learning

Motivation

Loss Function Diagram

Motivation

Zero-One Loss Function

Motivation

- An objective function is needed to select the "best" \hat{f} . An example is the zero-one loss.

$$\hat{f} = \operatorname{argmin}_f \sum_{i=1}^n \mathbb{1}_{\{f(x_i) \neq y_i\}}$$

- argmin_f objective (f) outputs the function that minimizes the objective.
- The objective function is called the cost function (or the loss function), and the objective is to minimize the cost.

Squared Loss Function

Motivation

- Zero-one loss counts the number of mistakes made by the classifier. The best classifier is the one that makes the fewest mistakes.
- Another example is the squared distance between the predicted and the actual y value:

$$\hat{f} = \operatorname{argmin}_f \frac{1}{2} \sum_{i=1}^n (f(x_i) - y_i)^2$$

Loss Functions Equivalence

Quiz

Loss Functions Equivalence, Answer

Quiz

Function Space Diagram

Motivation

Hypothesis Space

Motivation

- There are too many functions to choose from.
- There should be a smaller set of functions to choose \hat{f} from.

$$\hat{f} = \operatorname{argmin}_{f \in \mathcal{H}} \frac{1}{2} \sum_{i=1}^n (f(x_i) - y_i)^2$$

- The set \mathcal{H} is called the hypothesis space.

Activation Function

Motivation

- Suppose \mathcal{H} is the set of functions that are compositions between another function g and linear functions.

$$\left(\hat{w}, \hat{b}\right) = \underset{w, b}{\operatorname{argmin}} \frac{1}{2} \sum_{i=1}^n (a_i - y_i)^2$$

$$\text{where } a_i = g\left(w^T x + b\right)$$

- g is called the activation function.

Linear Threshold Unit

Motivation

- One simple choice is to use the step function as the activation function:

$$g(\square) = \mathbb{1}_{\{\square \geq 0\}} = \begin{cases} 1 & \text{if } \square \geq 0 \\ 0 & \text{if } \square < 0 \end{cases}$$

- This activation function is called linear threshold unit (LTU).

Sigmoid Activation Function

Motivation

- When the activation function g is the sigmoid function, the problem is called logistic regression.

$$g(\square) = \frac{1}{1 + \exp(-\square)}$$

- This g is also called the logistic function.

Sigmoid Function Diagram

Motivation

Cross-Entropy Loss Function

Motivation

- The cost function used for logistic regression is usually the log cost function.

$$C(f) = - \sum_{i=1}^n (y_i \log(f(x_i)) + (1 - y_i) \log(1 - f(x_i)))$$

- It is also called the cross-entropy loss function.

Logistic Regression Objective

Motivation

- The logistic regression problem can be summarized as the following.

$$(\hat{w}, \hat{b}) = \underset{w, b}{\operatorname{argmin}} - \sum_{i=1}^n (y_i \log(a_i) + (1 - y_i) \log(1 - a_i))$$

$$\text{where } a_i = \frac{1}{1 + \exp(-z_i)} \text{ and } z_i = w^T x_i + b$$

Optimization Diagram

Motivation

Logistic Regression

Description

- Initialize random weights.
- Evaluate the activation function.
- Compute the gradient of the cost function with respect to each weight and bias.
- Update the weights and biases using gradient descent.
- Repeat until convergent.

Gradient Descent Step

Definition

- For logistic regression, use chain rule twice.

$$w = w - \alpha \sum_{i=1}^n (a_i - y_i) x_i$$

$$b = b - \alpha \sum_{i=1}^n (a_i - y_i)$$

$$a_i = g(w^T x_i + b), g(\square) = \frac{1}{1 + \exp(-\square)}$$

- α is the learning rate. It is the step size for each step of gradient descent.

Perceptron Algorithm

Definition

- Update weights using the following rule.

$$w = w - \alpha (a_i - y_i) x_i$$

$$b = b - \alpha (a_i - y_i)$$

$$a_i = \mathbb{1}_{\{w^T x_i + b \geq 0\}}$$

Learning Rate Diagram

Definition

Other Non-linear Activation Function

Discussion

- Activation function: $g(\square) = \tanh(\square) = \frac{e^{\square} - e^{-\square}}{e^{\square} + e^{-\square}}$
- Activation function: $g(\square) = \arctan(\square)$
- Activation function (rectified linear unit): $g(\square) = \square \mathbb{1}_{\{\square \geq 0\}}$
- All these functions lead to objective functions that are convex and differentiable (almost everywhere). Gradient descent can be used.
